Iron Oxide Pigments

By Henry E. Stipp [1]

Sales of finished iron oxide pigments in 1972 increased to record levels as the result of a rapidly expanding business cycle. Demand for iron oxide pigments, especially manufactured yellow, was very strong. Increased utilization of yellow iron oxide pigment was attributed to its application in paint formulations to replace lead compounds such as lead chromate, or chrome yellow. Paint containing lead concentrations greater than 0.06% lead has been banned for use in household interiors after December 31, 1973, by the U.S. Food and Drug Administration.

Although imports of iron oxide pigments increased substantially, they were not sufficient to satisfy the strong domestic demand. Imports of iron oxide pigments were curtailed by the strong economic expansion that occurred in West European countries in 1972, and by the effects of dollar devaluation and U.S. price controls. Normally, imports supplement domestic production of iron oxide pigments and supply a significant part of the domestic market.

DOMESTIC PRODUCTION

Production of finished iron oxide pigments, as indicated by sales in 1972, increased 35.9% to a record 174,392 short tons. The value of finished iron oxide pigments in 1972 increased 30% to $40.3 million. Yellow iron oxide recorded the greatest percentage increase among the manufactured varieties, and metallic brown oxide showed the largest increase among the natural iron oxide colors. Twelve companies operated 18 plants in nine States in 1972. Pfizer, Inc. was the major producer, with plants in California, Illinois, and Pennsylvania.

Production of crude iron oxide pigments decreased substantially for the fourth consecutive year. Figures for production and sales were withheld in 1972 to avoid disclosing company confidential data. Five companies operating mines or plants in five States reported production of crude iron oxide pigments. The Cleveland-Cliffs Iron Co. produced the largest quantity from mines in Michigan.

Expansion of facilities by Pfizer, Inc. in Illinois and California was completed by August, and supplies of finished iron oxide pigments were expected to increase substantially by yearend.

Table 1.—Salient iron oxide pigments statistics in the United States

	1968	1969	1970	1971	1972

[1] Physical scientist, Division of Ferrous Metals.

CONSUMPTION AND USES

Consumption of iron oxide pigments increased sharply in 1972 as the result of high levels of paint, lacquer, and varnish sales. Record high construction activity for the second consecutive year and increased sales of automobiles, appliances and furniture reportedly were responsible for the increased consumption of paint, lacquer, and varnish. Shortages of some grades of iron oxide pigments occurred as a result of overall economic expansion, dollar devaluation, and price controls. Domestic supplies of yellow iron oxide were inadequate and imports were curtailed by decreased shipments from abroad. Foreign producers preferred to sell their products overseas where they could obtain a higher price. Several new paint formulas were introduced that incorporated yellow iron oxide and yellow organic pigments as a replacement for yellow lead chromate. Inventories depleted in the last quarter of 1971 were being replaced during most of 1972, however increased consumption slowed inventory rebuilding. Micaceous iron oxide, imported from Austria, was gaining increasing acceptance as a primer for protection of iron and steel structures against corrosion. A new group of red and yellow synthetic iron oxides became available for use in automobile finishes, aluminum coatings, and stains.

Iron oxide pigments were used in paints, rubber, plastics, concrete products, paper, magnetic ink, fertilizers, and animal food. They were used also in ferrite applications such as television components, filters in radio equipment, computer memory cores, door latches and seals, small electric motors, and inductor and microwave devices. Iron oxide material was used in miscellaneous applications such as abrasives, welding rod coatings, soil conditioners, foundry sands, and automobile brake linings.

Data are not collected by the Bureau of Mines on specific uses for iron oxide pigments, and the figures given in table 2 do not necessarily reflect all sales of iron oxide pigment material for uses other than pigments.

Table 2.—Finished iron oxide pigments sold by processors in the United States, by kind

[1] Includes black magnetite and Vandyke brown.
[2] Pyrite cinder included with red iron oxide for 1971 and 1972.
[3] Includes yellow iron oxide.

PRICES

Increases in price ranging from 1/2 cent per pound up to 1 1/2 cents per pound were reported effective March 1 on selected items of manufactured iron oxide pigments. Further increases in price ranging from 1/4 cent per pound to 2 1/2 cents per pound were reported effective July 28 on most items of manufactured iron oxide pigments. Natural iron oxide pigment prices remained steady throughout the year, with the exception of imported Vandyke brown, which increased by 3 1/2 cents per pound in October.

Table 3.—Prices quoted on finished iron oxide pigments, per pound, in bags, unless otherwise noted, as of December 31, 1972 [1]

FOREIGN TRADE

United States exports of iron oxide pigments in 1972 increased 7% to 4,268 short tons compared with exports of 3,984 short tons in 1971. Canada received the major share in 1972.

iron oxide pigments in 1972 increased 29.5% to 47,271 short tons compared with 36,496 short tons in 1971. The value of imports increased 38.6% in 1972 to $8.5 million compared with $6.2 million in 1971. Manufactured (synthetic) material constituted 72.5% of total U.S. imports. Crude and refined umber made up 63.4% of imports of natural iron oxide pigments. The major part of manufactured iron oxide pigments imported into the United States in 1972 came from West Germany, Canada, and the United Kingdom. U.S. imports of natural iron oxide came mainly from Spain, Iran, and France in 1972.

TECHNOLOGY

A method of selecting pigments for manufacturing powder coatings was described.[2] The final selection of a pigment was reportedly dependent upon end-use requirements, application method, proper resin system, and method of manufacturing. Pigment properties that entered into the selection process were color, heat stability, chemical reactivity, hiding power, particle size, surface area, oil absorption, electrical properties, migratory properties, and weatherability.

[2] American Paint Journal. The Colorful Choice In Powder Coatings. V. 56, No. 46, May 1, 1972, pp. 16–22.

Ferrites were proposed for use in identifying tanker ships involved in oil spills.[3] The ferrite powder would be introduced into the oil when the tanker took on its load of petroleum. Each batch of ferrites would have different magnetic properties. When an oil spill occurred, the various magnetic properties of the ferrites could be decoded and the polluting ship identified by the code assigned to it. During unloading of the oil cargo the suspended ferrites could be removed by a magnetic filter. Scientists estimate that 11 variations of the ferrite composition would yield 2,000 different codes. About 1 ton of ferrite material would be required for a 100,000-ton vessel.

Iron oxide powders of submicron size were prepared by precipitation of iron hydroxide with ammonium hydroxide from a solution of iron chloride. The colloidal precipitate was heat treated in a fluidized bed.[4] The iron oxide of submicron size gave superior performance when utilized as a pigment material in paint and when sintered with other metal oxides in preparing ferrite compounds.

A new ferrite material that was less sensitive to temperature changes was developed.[5] Lower memory core manufacturing costs and improved computer reliability was indicated by use of the new material. The new ferrite enables memory cores to operate from −25° C to 100° C without special temperature-controlling equipment.

A relatively low-cost process for regenerating pickle liquor with the production of iron oxide as a byproduct was reported.[6] Armco Steel Corp. started up a $4.25 million system at its Ashland, Ky., works that converts all the plant's spent pickle liquor into fresh hydrochloric acid. The system will regenerate about 90% of all the hydrochloric acid consumed at the Ashland works. Iron oxide is precipitated in the form of a fine powder of nearly pure grade. The process, sublicensed to Pennsylvania Engineering Corp., Pittsburgh, Pa., makes use of new technology and both plastic and titanium materials. Use of the process reportedly could save up to $7 per ton to dispose of the spent pickle liquor and $28 per ton for new hydrochloric acid. In addition, sale of the iron oxide would supplement the other savings.

Kyanite and Related Minerals

By J. Robert Wells[1]

Kyanite, andalusite, and sillimanite are anhydrous aluminum silicate minerals that are closely akin in both composition and use patterns and have the same chemical formula, $Al_2O_3.SiO_2$. Closely related materials include synthetic mullite, dumortierite, and topaz, also classed as aluminum silicates. The latter two additionally contain boron and fluorine, respectively. All of these substances have the capability of serving as materials for the manufacture of special-duty refractories of the high-alumina category. There has been no record in recent years, however, of significant utilization of either dumortierite or topaz for this purpose in the United States.

Although not enough statistics are published to be wholly conclusive, it appears that the United States, India, and the Republic of South Africa hold the lead among world producers of kyanite-group minerals and that they may be not far from evenly matched in that regard. Presumably, the U.S.S.R. and some other industrialized nations also produce significant quantities of these materials.

Domestic production of kyanite plus synthetic mullite dipped moderately in tonnage in 1972, the first such downturn since 1968. Total value of these two materials, which showed a steep drop in 1971 from the peak reached in 1970, sagged again in 1972, though less sharply. These declines may have resulted from the slackness in shipments of finished brick and shape kyanite-mullite refractories that was noted in the 1971 Minerals Yearbook chapter, a trend that was even more marked in 1972. Total value of shipments of mullite brick and shapes made predominately of kyanite-group minerals or synthetic mullite (exclusive of molten-cast products) was 10% lower in 1971 and 28% lower in 1972 than in 1970. Mullite-based mortars, ramming mixes, and castable refractories presumably held up well, because total value of all nonclay refractories followed a 6% decline in 1971 with a 12% increase in 1972.[2] In ample compensation for any reduction in domestic consumption of the mullite refractories, exports of kyanite and allied materials scored a spectacular increase in 1972 with regard to both quantity and total value. Kyanite imports, meanwhile, fell to their lowest level in over 30 years.

Legislation and Government Programs.—The 1970 revision of the list of strategic materials for stockpiling excluded kyanite-mullite. At that time Government holdings totaled approximately 4,800 short tons of that commodity, and Congress authorized the stepwise disposal of the entire quantity by public sale. Notices dated November 23, 1971, January 19, 1972, June 27, 1972, and October 27, 1972, invited bids for the as-is sale of portions of this material, but no acceptable offers were received.

The Office of Minerals Exploration offered to grant Government loans up to 50% of approved costs for the exploration of eligible kyanite deposits, but no loans for that purpose were made in 1972.

[2] U.S. Department of Commerce, Bureau of the Census. Current Industrial Reports, Series: MQ-32C; Summary for 1971; First, Second, Third, and Fourth Quarters 1972.

DOMESTIC PRODUCTION

Kyanite was produced in the United States in 1972 from three open pit mines, two in Virginia and one in Georgia. In addition to the hard-rock production, a minor quantity of kyanite-sillimanite concentrate was recovered in the process of extracting titanium and zirconium minerals from a beach sand deposit in Florida. Kyanite Mining Corp. operated the Willis Mountain mine in Buckingham County, Va., and the Baker Mountain mine in adjoining Prince Edward County, Va. C-E Minerals, Inc., operated the Graves Mountain mine in Lincoln County, Ga. E. I. du Pont de Nemours & Co., Inc., operated the Trail Ridge mine and mill in Clay County, Fla.

Domestic kyanite output in 1972, as measured by the quantity sold or used, was fractionally lower in both tonnage and total value than in 1971. Specific kyanite production statistics for 1972 (as well as for all previous years since 1949) are withheld because the predominant position of the two major producers would make publication of even national totals a disclosure of each firm's confidential data.

Synthetic mullite, produced in 1972 by eight companies at operations in seven States, amounted to 16% less in tonnage than in 1971 and 18% less in total value. The 1972 output consisted predominantly of high-temperature sintered material, the average unit value of which was substantially below that reported for fused material. Leading in tons produced were Babcock & Wilcox Co., Richmond County, Ga.; Mullite Corp. of America, Sumter County, Ga.; H. K. Porter, Inc., Fairfield County, Conn.; and Charles Taylor & Sons, Inc., Greenup County, Ky.; whose combined outputs amounted to 86% of the 1972 national total.

Table 1.—Synthetic mullite production in the United States

(Short tons and thousand dollars)

Year	Quantity	Value
1968	36,014	5,758
1969	48,588	6,847
1970	55,516	8,840
1971	55,077	4,945
1972	46,389	4,080

CONSUMPTION AND USES

Kyanite and related minerals, conforming to the established end-use pattern, were consumed in 1972 mostly in the manufacture of high-alumina or mullite class refractories and in lesser quantities as ingredients in some ceramic compositions. Imported Indian kyanite was calcined in its natural lump form, after which it was usually separated into designated particle-size ranges for use chiefly as a grog. Domestic kyanite already ground to minus 35 mesh, as required by the flotation process used in separating it from the accompanying quartz gangue, was marketed in the raw form or after heat treatment, as mullite, which was sometimes further reduced in particle size. In the 35- to 48-mesh range, the mineral was employed mostly in refractories applications such as for high-temperature mortars or cements, ramming mixes, and castable refractories, or with clays and other ingredients in refractory compositions for the making of kiln furniture, insulating brick, firebrick, and other refractory articles of a wide variety of types. More finely ground material, minus 200 mesh for example, was used especially in body mixes for sanitary porcelains, wall tile, precision casting molds, and miscellaneous special-purpose ceramics.

PRICES

Engineering and Mining Journal, December 1972, listed the following prices per short ton (unchanged from December 1971 quotations) for kyanite, f.o.b. Georgia, in bags (bulk shipments $2.00 less per ton):

	Per short tons
35 mesh	$58
48 mesh	62
100 mesh	65
200 mesh	73
325 mesh	Nominal

Prices and price ranges for kyanite-group minerals quoted by Industrial Minerals (London), December 1972, were as follows (after conversion from pounds sterling per long ton to dollars per short ton):

	Per short ton
Andalusite, Transvaal, c.i.f. main European port	$51–$56
Kyanite, Indian, c.i.f. main European port	65–79
Sillimanite, Indian, natural, f.o.b. Calcutta	83
Silimanite, Indian, calcined, f.o.b. Calcutta	94

FOREIGN TRADE

An impressively larger quantity of kyanite-group material was exported from the United States in 1972 (to a total of 23 countries) than in any previous year. Large shipments by sea in the year's last quarter, especially from Savannah, Ga., helped to bring the total tonnage to the highest point in history, more than double the 1971 figure. The average unit value of 1972 exports, $50 per short ton, compared with $65 to $70 per ton in recent years, hinted that a greater proportion of the material than in previous years may have been mullite derived from high-temperature calcination of clays, rather than by treatment of kyanite or by synthesis from SiO_2 and Al_2O_3 materials.

Kyanite-group imports in 1972 continued the downward slant that became evident in the early 1950's and declined to less than one-tenth of the 1971 figure and to less than one-fortieth of that of a decade ago, virtually ceasing to be an item of consideration in the U.S. trade balance. For the first time in may years, India was listed as the sole supplier.

Tariff regulations applicable throughout 1972 provided for the duty-free importation of kyanite, sillimanite, andalusite, and dumortierite. The duty on mullite, which amounted to 10% ad valorem in 1970, was reduced to 9% ad valorem on January 1, 1971 and to 7½% ad valorem on January 1, 1972.

Table 2.—U.S. exports and imports for consumption of kyanite and related minerals

	1970		1971		1972

[r] Revised.

WORLD REVIEW

Although in most cases little or no statistical information is available, significant production of kyanite-group minerals and materials in recent years has been reported in Australia, Brazil, France, India, Kenya, Malawi, Mozambique, Rhodesia, Republic of South Africa, Republic of Korea, Spain, Territory of South-West Africa, the United Kingdom, and the United States. Interest has been expressed in kyanite deposits in Canada and Norway also, but no commercial production has yet been recorded in those countries. The U.S.S.R. and others among the more industrialized countries doubtless either produce or consume substantial quantities of the kyanite minerals, but pertinent data have not been made public.

Australia.—The annual totals for Australian sillimanite production in the fiscal years ending June 30, 1969, 1970, and 1971, amounted to 2,137, 1,295, and 1,255 short tons, respectively.[3] Recovery of commercial quantities of kyanite and a number of other coproduct minerals is expected to be feasible when full-scale development is reached at a Du Pont sponsored ilmenite–rutile operation at Eneabba, 150 miles north of Perth in Western Australia. Discovery was announced of a potentially valuable kyanite deposit, also in Western Australia, and plans were made to establish facilities for its exploitation.

Canada.—Dumortierite was one of the minerals found to occur in significant amounts in a quartz-feldspar porphyry dike abutting the ore body at Canada's second-largest copper mine on the north end of Vancouver Island, British Columbia. Plans for commercializing the discovery were not mentioned.[4]

Germany, West.—Imports by West Germany of sillimanite minerals (including andalusite and kyanite) amounted to 43,000 tons in 1970 and 30,000 tons in 1971.

India.—Production of Indian kyanite decreased from 131,171 tons in 1970 to 92,638 tons in 1971. Production of sillimanite declined also, although less markedly, from 5,029 tons in 1970 to 4,722 tons in 1971. Exports accounted for 54% and 41% of the 1971 kyanite and sillimanite outputs, respectively. The United Kingdom, West Germany, Italy Japan, and the Netherlands were the principal recipients of the exported material. The Government of India announced that, as of April 1, 1972, all exports of sillimanite will be channeled through the state-owned Minerals and Metals Trading Corp. Mines in the Khasi Hills district of India's remote state of Assam are the world's foremost source of sillimanite, which is valued for the manufacture of special-purpose refractories that are denser and more resistant to abrasion and thermal shock than those based on synthetic mullite. High cost and limited supply, both occasioned by the inaccessibility of the deposits and the expense of transportation (first for long distances over difficult roads, then by river boat down the Brahmaputra to Calcutta) are cited as the principal influences restricting utilization of this mineral.

Israel.—An industrial journal published an article describing the installations and operations of Koors Industries, Hasin-Esh division, which manufactures mullite-type refractories from raw materials mined in Israel's Negev Desert. The resulting products are mostly consumed by the domestic steel, cement, chemical, and ceramic industries.[5]

South Africa, Republic of.—Output of kyanite-group minerals in 1971, the last year for which complete data are available, amounted to 49,020 tons of andalusite and 19,246 tons of sillimanite. Comparable figures for 1970 were 46,872 tons and 23,690 tons, respectively. Exports in 1971 accounted for 41% of the output of andalusite and exceeded that of sillimanite by 7%. Exports in 1970 amounted to 56% and 88% of the respective outputs.

United Kingdom.—The Highlands and Islands Development Board issued a report cataloguing observed mineral occurrences on Scotland's Isle of Skye and mainland Ross and Cromarty County. Kyanite was one of the minerals specifically listed, but no information was released concerning possibilities for commercial development.

TECHNOLOGY

In its annual review of materials for ceramic processing, an industrial journal presented informative thumb-nail studies of the kyanite-group minerals and their contributions to modern technology.[6] The research program of the Bureau of Mines included an investigation of beneficiation procedures applicable to kyanite-bearing materials from Idaho. A patent was issued for a process by which kyanite or other aluminosilicate ores can be treated with chlorine to volatilize undesired iron and titanium, leaving residues enriched in aluminum and silicon that can be smelted to produce alloys of these two elements.[7]

Mullite, synthesized from pure silica and Bayer-process alumina (at least 99% Al_2O_3) and then shaped into spheres, was the refractory catalyst-support base selected for a catalytic-cracking process for the production of synthetic pipeline gas.[8] A tabulation was published listing the physical, mechanical, and electrical properties, maximum recommended service temperatures, and practical applications of certain special-purpose ceramics of the refractory mullite type.[9]

A series of articles in a British journal presented a wide-ranging study of modern refractories and of the technology of their production and utilization. Prominently featured among the materials discussed were the kyanite–mullite group of refractories. Included in one of the reports was a useful world-wide listing of principal refractories manufacturers.[10]

A number of articles were published dealing with theoretical and experimental considerations of potential importance for the future development of kyanite–mullite refractories technology.[11]

An article reviewed technologic criteria for choosing types of refractories for a specified application. Considerations discussed for mullite and other applicable materials included thermal conductivity, thermal expansion, specific heat, emissivity, bulk density, porosity-permeability, thermal-shock resistance, creep, and crushing strength and modulus of rupture at different temperatures. More briefly treated were the topics of refractory life expectancy and comparative costs.[12]

The installations, equipment, and methods in use by a major producer of mullite refractories were subjects dealt with in a two-part magazine article.[13] New facilities for the development of refractories technology were placed in service by a leading industrial refractories manufacturer, Kaiser Refractories. The Clay-Alumina Development and Applications section of the new facility specializes in research on aluminosilicate materials, including mullite.[14]

Lead

By J. Patrick Ryan[1]

World production and consumption of lead reached record levels and achieved a near balance in 1972. Free world mine production increased about 1% with most of the net gain coming from the United States and Peru. Refined lead production was up nearly 2% with most of the major producing countries contributing to the increase. Consumption of metal rose 4%, the largest annual increase since 1969. The near balance between metal production and consumption brought relatively stable world market prices, particularly in the London Metal Exchange (LME) quotation. The average LME cash price published by Metals Week in terms of U.S. currency increased from 11.40 cents per pound in January to 14.51 cents in March, and generally declining thereafter to 13.98 cents in December. The average equivalent LME price in 1972 was 13.68 cents. The average U.S. producers' price after rising 1.6 cents to 15.60 cents in the first 5 months trended lower thereafter to 14.50 cents in December. The average domestic price of lead on a nationwide delivered basis in 1972 was 15.03 cents per pound.

The domestic lead industry again achieved significant gains in both mine production and consumption. Refinery production also increased continuing the rising trend of recent years after a falloff in 1971, which was attributed to a reduction in imports of crude materials for processing at domestic plants. Both mine and refinery production of lead reached the highest levels since 1929 with respective gains of about 7% over 1971 output. The 40,360-ton net increase in domestic mine output was achieved as gains in Missouri and Colorado more than offset declines in Idaho and Utah. Secondary lead output of 616,600 tons, representing about 39% of the market supply, was nearly 20,000 tons more than the 1971 output. The apparent domestic supply of lead consisting of primary, secondary, and imports (table 1) amounted to 1.57 million tons, 104,000 tons more than that of 1971.

Demand for lead in transportation uses continued to grow as requirements for batteries and gasoline antiknock compounds increased 7% and 5%, respectively. The quantity of lead used in battery manufacture reached a record high, and lead used in antiknock additives was only slightly below the record achieved in 1970. Lead used in pigments, reversing a 3-year decline, increased 10% in 1972. Of the total lead consumption of 1.48 million tons, batteries accounted for 49%; antiknock compounds, 19%; ammunition, 6%; pigments, 6%; and solder, 5%.

Stocks of refined and antimonial lead at primary plants increased from 52,100 tons at the beginning of the year to 64,500 tons at yearend. Consumer and secondary stocks declined from 125,600 tons at the beginning of the year to 118,500 tons at yearend. Commercial sales and transfers for government use, totaling about 49,800 tons, reduced the uncommitted government stockpile of lead to 1,077,600 tons at yearend.

St. Joe Minerals Corp. closed its Federal mine in October after 50 years of continuous operation thus phasing out mining operations in the Old Lead Belt of Southeast Missouri.

Legislation and Government Programs.—Commercial sales of surplus lead by General Services Administration (GSA) from the Government stockpile and transfers for government use totaled 49,825 tons in 1972 compared with only 12 tons in 1971. The disposals were authorized under Public Laws 91–46 and 89–9. Public Law 92–356 enacted on July 26 authorized 498,000 tons for disposal; 100,000 tons was authorized earlier under Public Law 91–46.

---

[1] Mining engineer, Division of Nonferrous Metals.

Actual drawdown of government stocks during 1972 was 44,738 tons, leaving a total of 1,085,871 tons remaining in the stockpile on December 31. Of the total uncommitted inventory at yearend 547,615 tons was in excess of the 530,000-ton objective.

GSA concluded contracts in May with primary producers for the disposal of 575,000 tons of surplus stockpile lead. Under terms of the contracts producers were obligated to purchase metal at the rate of 50,000 tons per year subject to suspension during quarters when producers' stocks exceed one-tenth of the preceding year's shipment of primary metal. The long-term contracts were amended at yearend by reducing the point of suspension to one-twelfth of the preceding year's shipments and increasing the purchase requirement to 55,000 tons per year. The new rates were to become effective January 1, 1973.

A bill (H.R. 16388) to provide for an adequate supply of lead and zinc for consumption in the United States from domestic and foreign sources was introduced in August and referred to the Committee on Ways and Means. The bill included a proposal to increase tariffs on lead in imported concentrates, lead and zinc unwrought and wrought metals, lead and zinc waste and scrap, and manufactures of these metals when exceeding specified limiting quantities. The bill also provided for revising the quotas for lead and zinc in concert with changes in the annual consumption. The proposed act was designed to implement the Mining and Minerals Policy Act of 1970 by encouraging private enterprise. No further action was taken on the bill by the 92d Congress. Bills (S. 3136, H.R. 12958) were introduced in the 2d Session, 92d Congress to regulate the amounts of lead and cadmium that may be released from glazed ceramic or enamel dinnerware; other bills introduced in the Congress relating to the use of lead included the following: S. 607—which would reduce the amount of lead contained in lead-based paints for residential use and establish procedures to minimize hazards of lead-based paint in any existing housing; H.R. 15937—which would provide performance standards for emission control devices to reduce air pollution from used vehicles, which could affect the use of lead in gasoline. The enactment of the Noise Control Act of 1972, which sets limits on noise emission, could stimulate the use of lead as a noise suppressing material in construction and other equipment.

On February 23 the Environmental Protection Agency (EPA) published guidelines

[1] Quotations for 1968–71 at New York and for 1972 on a nationwide, delivered basis.

in the Federal Register calling for a staged reduction in the lead content of gasoline and requiring that major oil companies provide at least one grade of unleaded gasoline—actually, 0.05 gram per gallon—by July 1, 1974. The proposed timetable for the reduction of lead in gasoline provided for a maximum lead content of 2 grams per gallon by January 1, 1974; 1.7 grams per gallon by January 1, 1975; 1.5 grams per gallon by January 1, 1976; and 1.25 grams per gallon by January 1, 1977.

[1] 1931–39 includes a small quantity of scrap.

DOMESTIC PRODUCTION

MINE PRODUCTION

Domestic mine output of recoverable lead continued its uninterrupted rise since 1967 with an increase of about 7% in 1972 to 618,900 tons. Monthly production reached a maximum of 56,900 tons in August, slightly more than the maximum achieved in 1971. Production from Missouri mines increased 59,800 tons to 489,400 tons, representing 79% of the total domestic mine output. Idaho, the second largest producing State, provided 10%; Colorado, 5%; and Utah, 3%.

The Buick mine of AMAX Lead Co. of Missouri was again the leading lead producer with an output of 189,000 tons of lead concentrate in 1972. The seven leading mines, all in Missouri, contributed 74% of the total domestic mine production of lead. The 10 leading mines produced 84%, and the 25 leading mines contributed nearly 99%.

St. Joe Minerals Corp. closed its Federal mine in October and reported that its new Brushy Creek mine in the New Lead Belt with a production potential of 50,000 tons of lead per year is scheduled to start milling early in 1973. Although St. Joe reported a 3% increase in lead concentrate production to 312,700 tons, output of lead and lead alloy declined 6% to 207,877 tons. Operations at the company's Herculaneum smelter were interrupted by a 2-week work stoppage.[2]

---

[2] St. Joe Minerals Corp. 1972 Annual Report. Pp. 9, 17.

Ozark Lead Co.'s Ozark mine produced 69,100 tons of lead in concentrates compared with 55,300 tons in 1971. The production gain reflected a return to full-scale operation following a production curtailment in 1971 because of a buildup of concentrates during the period when the Glover custom smelter was closed by a labor strike.

Production of lead in Idaho was 5,200 tons less than in 1971. Increased output at the Bunker Hill and Star mines did not fully offset the loss in output at the Lucky Friday mine. Hecla Mining Co. reported[3] ore production of 263,595 tons at the Star-Morning mine, owned jointly by Hecla (30%) and Bunker Hill (70%), about 17,000 tons more than in 1971. Hecla's share of the 1972 silver-lead-zinc ore production was 79,079 tons assaying 5.33% lead and yielding 3,854 tons of lead. Extensive deep level development was completed, including deepening of No. 4 shaft to the 7,900-foot level and approximately 4,150 feet of development footage. Hecla's share of computed ore reserves increased 4,000 tons to 265,000 tons at yearend. Hecla's Lucky Friday mine produced 192,020 tons of ore assaying 10.43% lead, compared with 213,390 tons assaying 11.3% lead in 1971. Ore reserves at yearend totaled 584,000 tons, about 32,000 tons more than 1 year earlier. The main shaft was deepened to 30 feet below the 4,250-foot level, and a pilot station crosscut was completed at the 4,250 level. Crosscuts were completed through the vein on the new 4,050 level.

Output of lead in Utah declined about 46% in 1972. The Mayflower mine operated by Hecla Mining Co. produced 114,604 tons of ore yielding 3,586 tons of lead compared with 4,860 tons in 1971. The mine was closed at yearend.

Kennecott Copper Corp. reported that output of lead increased at its Burgin mine in the Tintic District, Utah, in 1972 owing to improved working conditions and the discovery of a new ore zone. The critical shortage of skilled miners continued to hamper mine development and production.[4]

In Colorado lead output, continuing the rising trend since 1968, increased nearly 22% in 1972. As in 1971 the production gain was attributed largely to increased output at the Leadville Unit, an American Smelting and Refining Co. (ASARCO)—managed joint venture with Newmont Mining Corp. ASARCO reported that in the first full year of operation of the new shaft, the Leadville mine produced 208,000 tons of lead-zinc-silver ore and recovered 7,400 tons of lead compared with 4,000 tons in 1971.[5] The mill operated somewhat below its capacity of 700 tons of ore per day during the year, but with the greater development of the No. 5 ore body, near capacity production is expected in 1973. Ore reserves at yearend were estimated at 2,609,000 tons averaging 5.16% lead, 9.92% zinc, and 2.53 ounces of silver and 0.068 ounce of gold per ton. Idarado Mining Co. mined and milled 386,500 tons of lead-zinc-copper ore in 1972 compared with 391,300 tons in 1971. Ore reserves at yearend were estimated at 2.86 million tons averaging 3.31% lead, 4.80% zinc, 0.74% copper, and 0.03 ounce of gold and 1.75 ounces of silver per ton.[6]

SMELTER AND REFINERY PRODUCTION

Continuing the rising trend since 1967, output of lead at primary refineries increased 7% in 1972. Gains were recorded in metal recovered from both domestic and foreign concentrates. Production from domestic primary sources increased 19,000 tons, and from foreign sources the gain was 26,000 tons. The 696,800 tons of primary refined lead produced in 1972 was the largest total output since 1929. About 85% of the total production was derived from domestic ores compared with 88% in 1971. An additional 1,200 tons was refined from scrap. Antimonial lead production declined for the fourth consecutive year with only 14,000 tons of lead recovered, of which 6,100 tons originated from domestic ores, 2,100 tons from foreign ores, and 5,800 from scrap. The antimony content increased by 1.0% to 7.0%.

The Herculaneum, Mo., smelter of St. Joe Minerals Corp. produced 207,900 tons of lead metal and alloys, about 14,000 tons less than in 1971. The production decline resulted from a 2-week work stoppage in April.

[3] Hecla Mining Co. 1972 Annual Report. Pp. 7–8.

[4] Kennecott Copper Corp. 1972 Annual Report. P. 22.

[5] ASARCO. 1972. Annual Report. P. 7.

[6] Newmont Mining Corp. 1972 Annual Report. Pp. 8–9.

AMAX Lead Co. of Missouri reported that the smelter at Buick, Mo., jointly owned by AMAX and Homestake Mining Co., produced 133,000 tons of refined lead, compared with 109,000 tons in 1971. Of the total output 67,000 tons were for the account of AMAX-Homestake, and the remainder was processed on toll for other producers.[7]

ASARCO's custom smelting and refining plant at Glover, Mo., operating at less than capacity because of market conditions, produced 86,400 tons of lead compared with 66,500 tons in 1971, a year in which the smelter was shut down for nearly 4 months by a strike. Most of the concentrate treated at the Glover plant came from the Ozark Lead Co. mine at Sweetwater, Mo. Concentrates from 13 other domestic mines in five States and from one mine in Honduras also were treated at Glover. The East Helena, Mont., smelter operated continuously during the year processing crude ores and concentrates from approximately 54 domestic mines and mines in Canada, Peru, and Australia. The El Paso lead smelter processed ores and concentrates from about 28 domestic mines in seven States and from mines in Peru, Canada, Honduras, Nicaragua, Australia, and Mexico. Refined metal output at the company's Omaha refinery, which processed lead bullion from the East Helena and El Paso smelters, totaled 142,700 tons, 20,200 tons more than in 1971 when production was interrupted by a 7-week labor strike.

The Bunker Hill smelter-refinery of Gulf Resources & Chemical Corp. at Kellogg, Idaho, produced 131,000 tons of lead in all forms, 2% more than in 1971 and a new record. The corporation attributed the increase in lead production to improved operating techniques at the smelter.[8]

RAW MATERIAL SOURCE

Domestic mines delivered 619,000 tons of recoverable lead in concentrates to domestic primary smelters in 1972. This represents 88% of the plant production of 703,800 tons of primary refined and antimonial lead compared with 87% in 1971 and 84% in 1970. Lead recovered from imported concentrate smelted during the year amounted to 105,000 tons, about 24,100 tons more than in 1971. The 7,000 tons of lead recovered from lead scrap processed at primary plants was nearly double the 1971 total but constituted only 1% of the total lead from primary plants. Raw material stocks at the beginning of the year at primary plants totaled 165,500 of which 84,400 tons was in process and 1,800 tons was in secondary materials. Total stocks trended upward from a low of 163,800 tons at the end of January to a high of 204,000 tons at the end of November. At yearend, stocks of primary materials awaiting processing contained 92,900 tons of lead, material in process 101,900 tons, and secondary materials 2,500 tons, making a total of 197,300 tons.

Scrap materials consumed in 1972 totaled 814,400 tons, nearly 30,000 tons more than in 1971. New scrap in the form of purchased drosses and residues from a wide variety of sources aggregated 158,900 tons, about 19% of the total input. The remainder, old scrap, was predominantly battery scrap with small amounts of cable lead, type metal, solder, babbitt, and soft and hard lead. The scrap processed was essentially all from domestic sources. General imports of reclaimed scrap, mainly from Australia, totaled 3,200 tons (lead content), slightly less than in 1971, but exports of lead scrap totaling 35,200 tons were about double those in 1971. Stocks of scrap at smelters at yearend were nearly 66,300 tons, about 7,300 tons less than at yearend 1971.

CONSUMPTION AND USES

Lead consumption in the United States increased nearly 4% in 1972 to a new record of 1.48 million tons. Monthly requirements were higher than those of 1971 in every month except July and September. All major product categories required greater quantities of lead than in 1971. In the metal products category, the 46,800-ton (7%) increase in battery requirements more than offset decreases in the quantity of lead used in ammunition, cables, calking, tubes, sheet lead, and other products. The growth in battery lead requirements largely reflected continued increase in the population of both on-the-road and off-the-road motor vehicles using battery power for starting, lighting, ignition, and propulsion. A total of 55.5 million automotive batteries were produced in 1972, about 43.2 million of which were required for replacement and the remainder for new car production. The growth in antiknock requirements was resumed in 1972 after a 5% decrease in 1971. The quantity of lead used in gasoline antiknock compounds increased 5% to 278,340 tons, only slightly less than the record consumption in 1970. The gain in lead antiknock additives reflected continuing growth in gasoline production and an increase in the average lead content per gallon of gasoline, from 2.59 grams per gallon in 1971 to 2.63 grams per gallon in 1972.

---

[7] AMAX. 1972 Annual Report. P. 17.

[8] Gulf Resources & Chemical Corp. 1972 Annual Report. P. 23.

Soft refined lead represented 65% of the total consumption, antimonial lead 29%, and lead in other alloys, mainly solder and bearing metals, accounted for 5%. Lead in copper-base scrap accounted for 1% of consumption.

The domestic supply of lead metal from all sources—production, imports for consumption, stock changes, and stockpile releases—totaled about 100,000 tons more than reported consumption and exports. The unaccounted for supply in 1972, amounting to about 7% of reported consumption compares with an annual average of approximately 64,000 tons for the 1963–72 period. The difference in totals is attributed to unreported consumption and stock buildup, especially by small users and dealers that do not report to the Bureau of Mines.

The compound annual growth rate in lead consumption during the 10-year period 1963–72 averaged about 2.5% owing largely to the increased demand from the transportation sector for batteries and gasoline additives, which together showed an annual growth of 4.8% and accounted for approximately 68% of the total domestic consumption in 1972, but only 54% in 1963.

Pigments and weights and ballast uses also showed significant growth, but lead consumption in most other metal products was less than in 1971. In 1963 the use of lead in various products in terms of percent of total was as follows: Batteries 39%, other metal products 32%, pigments 8%, chemicals including antiknock compounds 17%, and miscellaneous and other unclassified uses 3%. In 1972, the comparative percentages were as follows: Batteries 49%, other metal products 23%, pigments 6%, chemicals including antiknock compounds 19%, and miscellaneous and other unclassified uses 3%.

LEAD PIGMENTS

Lead requirements for the production of lead oxides and pigments totaled 450,900 tons, about 6% more than in 1971. The quantity of lead used in making white and red lead was virtually the same as in 1971 and constituted about 6% of the total lead consumed in pigments. White lead requirements in 1972 were little more than one-half those 10 years ago, whereas the quantity used in red lead was only slightly less. Litharge production and shipments were about the same as in 1971 but were substantially greater than in 1963. Most of the litharge shipments went to battery manufacturers and is included in "Other." This category comprising 77% of the total shipments has increased from 72,400 tons in 1963 to 113,700 tons in 1972. Litharge for use in ceramic glazes amounting to 16% of the total shipments was slightly less than in 1971.

Shipments of white lead exceeded production, but red lead shipments were less than production. In 1972, shipments of litharge continued to exceed production for the eighth consecutive year, indicating a continued drawdown in stocks.

Prices.—Although more frequent then in 1971, lead pigment price changes were relatively moderate during the year. The price of basic carbonate white lead in carload lots, freight allowed, remained virtually unchanged at 22.3 cents per pound during the first 6 months. In July the price was increased to 23.9 cents per pound and remained unchanged thereafter to yearend. The quoted price of red lead oxide (Pb_3O_4) in carload lots, at works, was advanced from 17.75 cents in January to a range of 18.50–18.95 cents in February, 18.95–20.45 cents in May and 20.0–20.45 cents in June, remaining unchanged to October when the price quotation was reduced to 19.25 cents. The price was reduced again in December to a range of

18.75–18.90 cents. The price quotation of commercial-grade litharge, powdered, in carload lots, at works, ranged between 17.75–18.00 cents per pound and 19.25–19.50 cents during the year and was 18.00 cents at yearend, the same as at the beginning of the year.

The value of shipments of white lead, red lead, and litharge amounted to $61.1 million, an average of $344 per ton compared with $57.1 million and $325 per ton, respectively, in 1971.

Foreign Trade.—Exports of pigment-grade lead oxides total 1,866 tons valued at $818,400 and exports of lead oxides other than pigment grade amounted to nearly 500 tons valued at $455,600. Shipments went to about 36 countries. Canada, South Vietnam, West Germany, Italy, Japan, and Trinidad were the leading importers of pigment-grade lead oxide, accounting for 80% of the total. Canada, West Germany, Japan, and Netherlands received nearly 85% of the nonpigment-grade oxide exported.

Imports for consumption of lead pigments and compounds decreased 5% in quantity but increased 21% in value to $9.2 million. Litharge which comprised 58% of the total imports increased 4%, but imports of red lead decreased 74%. Mexico supplied nearly all of the 15,360 tons of litharge and 1,290 tons of red lead imported.

STOCKS

Inventories of refined and antimonial lead at primary smelters and refineries declined through the first 4 months as shipments exceeded production then increased steadily through September falling off again at yearend. Metal stocks totaling 52,100 tons at the start of the year increased to 64,500 tons at yearend. Stocks of base bullion declined about 2,300 tons during the year, but ore and matte stocks increased 13,800 tons.

Stocks of lead in all forms at consumer and secondary smelting plants totaled 118,500 tons at yearend, which reflects a 7,000-ton reduction during the year. Refined soft lead constituted 62% of the total compared with 65% of the total in 1971.

Stocks of lead at producers and consumers plants totaling about 264,000 tons, represented slightly more than 2 months' domestic consumption.

PRICES

Although the quoted price range of common-grade lead on a nationwide delivered basis was 14.0 to 14.3 cents, the producer price based on the weighted average of domestic sales as reported by Metals Week remained unchanged through January at 14.0 cents per pound. Two price changes in February raised the price to 15.5 cents, which held until mid-April when a split quotation of 15.5 to 16.0 cents again developed because some producers raised their price. The average price in April and May was 15.6 cents. Thereafter an average price of 15.5 cents held until late in August when one major producer lowered its price 0.5 cent to 15.0 cents and the split quotation became 15.0 to 16.0 cents. In mid-October the quoted price range became 14.5 to 16.0 cents when one producer reduced its price 0.5 cent to 14.5 cents. The price reduction reflected an increased supply situation attributed to gains in imports, metal inventories, and GSA releases. The split price quotation of 14.5–16.0 cents per pound continued unchanged through December; however, virtually all sales were made at 14.5 cents. Hence the weighted average producers' price of lead at yearend was 0.5 cent more than at the beginning of the year. The spread between the average domestic price of lead and the average equivalent London Metal Exchange (LME) spot quotation narrowed during the year from 2.6 cents in January to 1.4 cents in September and 0.5 cent in December. The average weighted domestic price for the year was 15.0 cents per pound.

The LME average spot quotation trended upward from a low of £97.80 per metric ton in January to £123.79 in September and to £131.39 in December. The equivalent price in terms of U.S. dollars was 11.40 cents per pound in January, 13.71 cents in September, and 13.98 cents in December; the average for the year was 13.68 cents (using a Sterling exchange average of 250.08 cents) compared with an average price of 11.52 cents in 1971.

The relative stability in the domestic price of lead in 1972 was attributed largely to the near balance between supply and demand during most of the year. Some softening of the market developed whenever excess inventories developed in relation to metal consumption. Selling prices for lead were well below the price ceiling of 16.5 cents established under U.S. price control regulations.

FOREIGN TRADE

Exports of lead materials during 1972 aggregated 43,600 tons valued at $8.8 million, compared with 23,000 tons valued at $6.2 million in 1971. Wrought and unwrought metal constituted 19% of the total exported; the remaining 81% was contained in scrap materials, most of which was shipped to Canada.

Reversing the declining trend since 1967, general imports of lead materials increased 31% in 1972 to a total of 348,000 tons valued at $84.5 million. Receipts of lead in concentrates and other crude materials were about 36,000 tons more than in 1971 and metal receipts increased 46,800 tons to nearly 242,400 tons. The quantity of lead in ores and concentrates received exceeded the quantity entered duty paid for consumption by nearly 50,000 tons, indicating a buildup of lead ores in bond. Canada continued to be the leading supplier of crude lead materials with 30% of the total, followed by Peru, Australia, and Honduras. Canada also continued to be the leading metal supplier with 34% of the total followed by Peru 20%, Australia 15%, Mexico 15%, and the United Kingdom 5%.

WORLD REVIEW

In 1972 mine production of lead in non-Communist countries (including Yugoslavia), depending on the reporting base and source, and scope of estimating, ranged from 2.89 million tons based on data compiled by the Bureau of Mines, through the International Lead and Zinc Study Group preliminary total of 2.82 million tons to the American Bureau of Metal Statistics (ABMS) total of 2.73 million tons. Bureau of Mines data, which indicate the basis used insofar as possible, depend largely on government information, as do those of the Study Group, although a somewhat different basis is used by the Study Group. ABMS relies largely on company and industry association sources. The Bureau of Mines estimated production in Communist countries (excluding Yugoslavia) at 0.96 million tons and the world total at 3.85 million tons, an alltime record high. Smelter output of lead is reported by the Bureau of Mines as primary output, insofar as possible, whereas the Lead and Zinc Study Group reports metal output from both primary and secondary sources. Thus, smelter output in 1972 in non-Communist countries, ranged from the Study Group preliminary total of 3.32 million tons through the ABMS total of 2.95 million tons to the Bureau of Mines total of 2.77 million tons. In addition the Bureau of Mines estimated 0.95 million tons of metal produced in Communist countries (excluding Yugoslavia) to provide a world total of 3.73 million tons of primary lead. The ABMS estimate for the same Communist countries was 1.07 million tons for a world smelter production of 4.02 million tons of lead.

The United States maintained its rank as the leading mine producer of lead in 1972, accounting for approximately 16% of the world total, followed by the U.S.S.R., Australia, Canada, Peru, Yugoslavia, and Mexico each with production exceeding 100,000 tons of lead in ore mined; these seven countries produced 67% of the world total. Non-Communist country lead output increased about 2% because production gains from mines in the United States, Peru, and Yugoslavia more than offset the loss in Canada. The North America area increase was about 3% and the 1.24 million tons produced represented 43% of the non-Communist country total and 32% of the estimated world total.

The United States also continued to be the leading producer of primary lead metal as well as secondary lead. The U.S.S.R. again ranked second, followed by Australia, Japan, Canada, Mexico, France, West Germany, People's Republic of China, and Spain. The 10 countries each produced more than 100,000 tons and together accounted for 72% of the world total. The North America area accounted for 34% of the non-Communist country metal output and 29% of the estimated world output (excluding U.S. secondary production). The 8% gain in non-Communist country primary metal output came chiefly from increases in the United States, Canada, Mexico, Peru, France, Spain, Australia and Japan. The smelter output data for some countries, particularly France, Japan, and West Germany, includes secondary metal.

According to preliminary data compiled by the International Lead and Zinc Study Group (ILZSG), non-Communist country consumption of lead in 1972, including primary and secondary metal, amounted to 3.73 million tons, about 5% more than in 1971. Most of the increase came from European countries. ILZSG non-Communist country comparative statistics on metal production and consumption indicate a supply deficit of about 74,000 tons in 1972 compared with an indicated surplus of nearly 16,000 tons in 1971. However, the indicated production deficit was not reflected in producers' stocks, which increased about 40,000 tons during the year to 266,000 at yearend. Consumer's stocks in the United States, United Kingdom, and Japan combined declined about 4,300 tons to 145,000 tons at yearend.

Trade data for the first 9 months of 1972 compiled by ILZSG disclosed that imports of lead bullion and refined lead into Socialist countries from the rest of the world totaled about 45,000 tons, 3,000 tons more than exports.

Algeria.—Société Nationale de Recherche et d'Exploitation Minière (Sonarem), the Algerian state mining agency, initiated an expansion and reconstruction program at the El Abed lead-zinc mine to increase production from 800 to 3,300 tons per day. The El Abed ore body is an extension of the Bou Beker-Touissit ore deposit across the border in Morocco. Total ore reserves at El Abed were estimated to contain 68,000 tons of lead and 391,000 tons of zinc.

Australia.—Mine production of lead increased nearly 2% to 451,000 tons. The production gain was largely attributed to increased output at Broken Hill mines and at the Rosebery mine in Tasmania.

M.I.M. Holdings Ltd. reduced production of silver-lead-zinc ore at its Mount Isa operations nearly 12% to 2.20 million tons and recovered about 127,800 tons of lead, 31,000 tons less than in 1971. The average lead content of the ore treated was 6.9% compared with 7.2% in 1971. The lead smelter operated well below design capacity throughout the year. In June 1972 the company reported silver-lead-zinc primary ore reserves in the Mount Isa mine at 61.7 million tons averaging 4.8 ounces silver per ton, 6.9% lead, and 6.3% zinc. At the Hilton mine primary silver-lead-zinc ore reserves were estimated at 39.2 million tons averaging 5.8 ounces silver per ton, 7.7% lead, and 9.6% zinc.[9]

Broken Hill South Ltd. treated 216,200 tons of ore averaging 9.7% lead, 6.7 ounces silver per ton, and 8.5% zinc and produced 29,000 tons of lead concentrate averaging 68.7% lead, 44.7 ounces silver per ton, and 4.9% zinc. In addition, the company treated 224,100 tons of dump material assaying 2.8% lead, 3.2 ounces silver per ton, and 4.1% zinc and produced 3,230 tons of lead and 366,100 ounces of silver in lead concentrate and 5,950 tons of zinc in zinc concentrate. The lead concentrates produced by the company were sold to the Broken Hill Associated Smelters, Pty. Ltd. (BHAS) at Port Pirie. In addition to copper and zinc the company's operation at Cobar produced 3,660 tons of lead concentrate assaying 45.7% lead from the treatment of copper-zinc ore. The company closed its South mine in July after 87 years of operation.

E.Z. Industries Ltd. (Electrolytic Zinc Co. of Australia Ltd.) continued to expand production at its Rosebery mine in Tasmania. During fiscal year 1972 the company milled 473,800 tons of zinc-lead-copper ore and produced about 24,000 tons of lead concentrate, a 54% gain in ore milled and a 75% gain in output of lead concentrate compared with production in fiscal year 1971. The expansion program to double production was virtually completed during the fiscal year.

---

[9] M.I.M. Holdings Ltd. 1972 Annual Report. Pp. 5–6.

Lead production at the Port Pirie smelter operated by BHAS was 207,200 tons, a gain of 18,700 tons over 1971 output attributable largely to uninterrupted operations and absence of labor strikes during the year.

At the New Broken Hill Consolidated Ltd. (NBHC) mine at Broken Hill 1.26 million tons of lead-zinc-silver ore averaging 7.9% lead, 13.6% zinc, and 2.0 ounces silver per ton was milled to produce 124,000 tons of lead concentrate containing 94,000 tons of lead, and 2.0 million ounces of silver. The gain of 7% in concentrate production reflected increased ore production due to the absence of industrial stoppages during the year and slightly higher ore grade. At the Zinc Corp. Ltd. (ZC) mine the company milled 920,000 tons of ore averaging 10.9% lead, 10.6% zinc, and 2.9 ounces silver per ton and produced 126,000 tons of lead concentrate containing 96,000 tons of lead and 2.1 million ounces of silver, virtually the same as in 1971. Estimated fully developed ore reserves in the NBHC mine at yearend were 7.28 million tons assaying 9.1% lead, 14.0% zinc, and 2.3 ounces silver per ton. In the ZC mine estimated ore reserves remained virtually unchanged at 6.83 million tons averaging 11.6% lead, 9.8% zinc, and 2.5 ounces silver per ton.

Sulphide Corp. (Pty.) Ltd. produced 30,200 tons of lead bullion at its Cockle Creek smelter, a gain of 3,400 tons over 1971 output. The company's output of zinc, sulfuric acid, and cadmium also increased in 1972.

North Broken Hill Ltd. reported that it mined 563,470 tons of ore during fiscal 1972. The ore assayed 13.0% lead, 10.0% zinc, and 6.8 ounces silver per ton, and production was 95,860 tons of lead concentrate containing 70,100 tons of lead. Ore reserves were estimated at 5.0 million tons.

Canada.—Canadian mine output of lead contained in ores and concentrates declined 3% in 1972 from the record production in 1971. The decrease in output was attributed largely to labor strikes at Cominco Ltd., and Heath Steele Mines Ltd. Mattabi Mines Ltd. began production operations in July, and Manitou-Barvue Mines Ltd., resumed production in June after an 8-month shutdown because of low metal prices. Cominco Ltd. announced the reopening of its H.B. mine in 1973 which will operate at a rate of 1,000 tons per day. Cominco also reported that underground development continued at the Cominco-Bankeno zinc-lead deposit on Little Cornwallis Island to confirm ore reserves estimated at 24 million tons averaging 24% combined lead and zinc. Nigadoo River Mines Ltd. suspended operations following a labor strike and Dresser Minerals, a division of Dresser Industries Inc., announced the closing of its lead-zinc mining operations in August.

Two Provinces, British Columbia and New Brunswick, and the Yukon and Northwest Territories together accounted for nearly 70% of Canada's total mine output of lead.

Primary lead output from refineries at Trail, British Columbia, operated by Cominco Ltd., and at Belledune, New Brunswick, operated by Brunswick Mining & Smelting Corp. Ltd. increased about 12% to 208,600 tons. Conversion of the Belledune smelter from an Imperial Smelting Process (ISP) plant to a straight lead smelter will, when completed and additional equipment installed in 1973, increase lead refining capacity about 82% to 60,000 tons per year.

Exports of lead in ores and concentrates declined 10% to 178,500 tons compared with 199,200 tons in 1971. Shipments to Japan increased, but shipments to other countries declined. Refined metal exports totaling 140,700 tons were about 3% more than in 1971. Shipments to the United States which accounted for 59% of the total increased 45%. Small increases in shipments to the United Kingdom and the Netherlands also were recorded, but shipments to other countries declined.

Heath Steele Mines Ltd., jointly owned by AMAX and International Nickel Co. of Canada Ltd. (Inco), treated 836,000 tons of lead-zinc-copper ore at its New Brunswick mill and produced 22,000 tons of lead concentrate along with zinc and copper concentrate compared with 45,000 tons in 1971. The decline in mill output was attributed to an 8-week strike and to a lower grade of ore. The company began an $11 million expansion program scheduled for completion in 1975 that will increase mine and mill production by approximately one-third and improve metallurgical recoveries.[10]

Anvil Mining Corp. Ltd. completed the third year of operation at its open pit mine and concentrator in 1972 and reported the sale of concentrate containing 103,560 tons of lead plus zinc and silver. The company reported an increase in the average concentrator throughput to nearly 8,000 tons per day with a grade of 10.8% combined lead and zinc. Ore reserves at yearend were estimated at 55 million tons averaging 8.86% combined lead and zinc with 1.1 ounces of silver per ton.

Brunswick Mining and Smelting Corp. Ltd. reported that it milled 3,257,600 tons of lead-zinc-copper ore yielding 172,900 tons of lead concentrate, 320,800 tons of zinc concentrate, and 17,600 tons of copper concentrate. An increase of 218,000 in tons treated combined with an increase in average grade of 0.27% to 9.92% combined lead and zinc resulted in a record high output of concentrate. Preliminary conversion of the zinc-lead ISP smelter to a smelter treating only lead concentrate was made in January. Additional modifications in sintering and crushing and refining facilities to increase capacity were begun in mid-October; operations were scheduled to be resumed early in 1973. Although smelter modification reduced operating time to less than 9 months, production of refined lead increased 13,560 tons to 35,980 tons. Reserves of lead-zinc ore in the No. 12 mine at yearend were estimated at 73.5 million tons averaging about 3.8% lead, 9.4% zinc, 0.27% copper, and 2.8 ounces of silver per ton.[11]

ASARCO reported that production of lead, zinc, and silver at its Buchans mine in Newfoundland was almost double 1971 output when a 21-week strike interrupted operations. Byproduct lead from the Ecstall Mining Co. Kidd Creek mine in Ontario and from United Keno Hill Mines Ltd. mine operations in the Yukon also contributed to Canada's total lead output.

Cominco Ltd., continued to operate the Sullivan mine in British Columbia, the Pine Point mine in the Northwest Territories and the Trail smelter which treated company and custom lead-zinc ores. Ore production at the Sullivan mine was 1.92 million tons with a combined lead-zinc grade of 10.8% compared with 1.98 million tons averaging 11.3% in 1971; Pine Point ore production was 3.81 million tons averaging 8.9% combined lead-zinc and yielding 119,000 tons of lead concentrate and 391,000 tons of zinc concentrate, most of which was shipped to the Trail smelter. The company began work preparatory to reopening the H.B. lead-zinc mine near Trail. The mine and concentrator, which had been closed since 1966, was scheduled for production early in 1973. Lead production at Trail from all sources totaled 170,000 tons compared with 163,000 tons in 1971. Ore reserves at the Sullivan and H.B. mines totaled 63.0 million tons containing 6.9 million tons combined zinc and lead; and Pine Point reserves totaled 41.0 million tons containing 3.4 million tons of zinc and lead.[12]

Honduras.—New York and Honduras Rosario Mining Co. reported that it treated a record tonnage of ore at its El Mochito mine and established a record production of lead, zinc, and cadmium, and only slightly less silver than in 1971. The mill processed 314,000 tons averaging 8.0% lead, 9.4% zinc, and 11.7 ounces of silver per ton and recovered lead concentrates containing 19,825 tons of lead along with silver, gold, and zinc. Assured and probable ore reserves in the main mine area at yearend were 1.94 million tons grading 10.7% lead, 11.5% zinc, 12.3 ounces of silver and 0.007 ounce of gold per ton. The 7% decrease in reserves reflected the emphasis placed on deep-level development, including shaft sinking below the 1,725 level and preparation of the new working levels and reduced amount of development for new ore. Exploration and development of the San Juan ore body have increased overall ore reserves by 2.84 million tons grading 2.7% lead, 6.9% zinc, 0.3% copper and 2.6 ounces of silver per ton. Mining of this ore body is scheduled to begin in 1974, and further expansion of milling facilities is planned to accomodate increased ore production.

India.—In 1972 Hindustan Zinc Ltd. (HZL) produced 346,500 tons of zinc-lead ore at its Zawar mine, and recovered 4,980 tons of lead concentrate, a moderate increase over output in 1971. The concentrate was processed at the company's smelter at Tundov, Bihar, and about 2,900 tons of lead metal recovered, only 49% of the smelter's rated capacity compared with 1,700 tons in 1971. Plans to expand ore production to 2,000 tons per day announced in 1971 were not implemented.

[10] Page 17 of work cited in footnote 7.

[11] Brunswick Mining and Smelting Corp. Ltd. Twentieth Annual Report. 1972. Pp. 6–7.

[12] Cominco Ltd. 67th Annual Report. 1972, pp. 8–9.

During 1972 imports of lead totaled 43,900 tons. According to the Planning Commission India's metal availability in 1972 totaled 55,000 tons compared with estimated demand of 97,500 tons indicating a supply shortfall of 42,500 tons.

Ireland.—Tara Exploration and Development Co. Ltd. reported significant progress on the underground development of its Navan lead-zinc ore body comprising sinking an access shaft and driving a decline tunnel. Design of plant facilities advanced according to plan, and construction was scheduled to start late in 1973; initial production was scheduled to begin by mid-1975. The Navan ore body is currently estimated to contain reserves totaling 77 million tons averaging 2.62% lead and 10.99% zinc. Initial plans include a vertical three-compartment development shaft and a service tunnel declined at approximately 20%. Trackless load-haul-dump vehicles will be used, and primary crushing will take place underground. Ore will be hoisted from the mine through a production shaft from a depth of about 1,000 feet. The concentrator will have an initial design capacity of 7,500 tons per day. The annual output when the mine is in full production will amount to about 466,000 tons of concentrate containing 265,000 tons of zinc and lead in the approximate ratio of 5 to 1. The total capital cost to bring the mine into production is estimated at $85 million, representing the largest single capital investment by private industry in the Republic of Ireland.[13]

Irish Base Metals Ltd. at Tynagh milled 587,233 tons of ore, which yielded 45,200 tons of lead, 30,800 tons of zinc, and 2,050 tons of copper. Primary sulfide ore reserves at yearend were 410,000 tons, averaging 8.0% lead, 3.4% zinc, 0.7% copper, and 3.8 ounces of silver per ton.

Mexico.—ASARCO Mexicana, S.A., 49% owned by ASARCO, reported that its mines and plants operated normally during 1972, with the exception of the Chihuahua lead smelter, which continued to experience technical problems with its updraft sintering plant. The company's mine development program brought favorable results. Implementation of the expansion program at the Taxco unit advanced with the installation of new hoisting equipment and headframe, shaft sinking, and preparation of surface sites for the new mine and related facilities. The company produced 75,600 tons of lead, about 2,200 tons more than in 1971.[14]

Morocco.—Lead production in 1972 increased 11,412 tons to 97,392 tons, of which 33,600 tons came from the Zaida mine in its first full year of operation. Exports of lead rose by about 50% to 151,400 tons, most of which was shipped to France. New reserves at Touissit were estimated at 3.4 million tons averaging about 14% lead. Production is expected to begin in mid-1974.

Nicaragua.—Neptune Gold Mining Co., controlled and operated by ASARCO, achieved near-capacity production at its Vesubio lead-zinc mine during its first full year of operation. Output of lead in concentrates was 2,200 tons compared with 600 tons in 1971. The grade of ore mined from the upper levels of the mine was below the average that will be obtained when lower levels are fully developed for production.

Peru.—Cerro Corp. reported that its Cerro-Peru operations were relatively free of labor strike interruptions during 1972, which resulted in a substantial increase in output of lead, zinc, and copper at its mines and refineries. Refined lead production was nearly 94,300 tons, about 19,300 tons more than in 1971. The corporation operated six mines and related metallurgical facilities—Cobriza, Cerro de Pasco, Yauricocha, San Cristobal, Casapalca, and Morococha. The Cerro de Pasco mine, predominately a producer of lead-zinc-silver ore, treated 1.9 million tons partly from the McCune open pit and partly from underground. The Yauricocha mine treated approxiately 480,000 tons of copper-lead-silver ore at its concentrator, and the San Cristobal mine treated about 570,000 tons of copper-lead-zinc-silver ore. The Casapalca and Morococha mines treated about 600,000 and 550,000 tons of copper-lead-zinc-silver ore, respectively. In 1972 about 47% of Cerro-Peru's refined lead production came from purchased ores, 40% came from purchased ores in 1971.

---

[13] Tara Exploration and Development Co. Ltd. Annual Report. 1972. Pp. 3, 6–7, 9.

[14] Pages 7 and 13 of work cited in footnote 5.

Yugoslavia.—Trepča Corp. expansion and modernization of production facilities at its Stari Trg mine continued during the year. When completed in 1975, the expansion program will increase ore production capacity to 440,000 tons per year and metal production to 184,000 tons of lead per year.

TECHNOLOGY

Most of the research and development effort in the lead industry continued to be market-oriented with emphasis on maintaining growth in established uses and in developing new applications that will offset a declining trend in some areas where substitution and environmental restrictions have become significant factors. Further progress was made in developing automotive emission control technology and equipment that will be effective in reducing lead and other exhaust pollutants in compliance with standards established under the Clean Air Act of 1970.

A dual-bed catalytic device designed by Gould, Inc., to meet auto exhaust emission control standards for carbon monoxide, hydrocarbons, and nitrogen oxides was undergoing tests by leading automobile and antiknock-additive manufacturers to determine the catalysts effectiveness and compatibility with leaded gasoline. The company stated that the first catalyst in the dual-bed system not only is effective in reducing nitrogen oxides but facilitates the action of the second oxidation catalyst which removes most of the carbon monoxide and hydrocarbons to meet emission standards.

The National Academy of Sciences (NAS) in a report to Congress and the Environmental Protection Agency stated that the Honda dual-carburated, stratified charge system, which is not sensitive to leaded gasoline, was the most promising of the five systems under evaluation by automobile manufacturers. The Honda system was reported by NAS to be clearly superior to the noble metal catalyst system. NAS also stated that the Honda system offers the promise of lower initial costs, greater durability in service, and significantly greater fuel economy compared with the catalyst system. The stratified charge engine achieved well over the 90% reduction in hydrocarbon and carbon monoxide emissions, called for in the Clean Air Act, after 50,000 miles of durability testing. Some uncertainty exists as to whether the same degree of emission control achieved in smaller engine sizes could be mass produced for larger conventional engines by 1976.

The International Lead Zinc Research Organization (ILZRO) continued to sponsor and conduct research programs on a worldwide basis with emphasis in those areas that will have a strong impact on markets. The shortage and steeply rising price of lumber coupled with increasing labor costs has prompted strong efforts by ILZRO to produce lower cost prefabricated all-metal housing units in which lead and zinc will have major roles. The ILZRO house is designed to provide a basic moderately priced core unit that can be expanded as required, and will include such new developments as lead-plastic composites and lead sheet for sound attenuation in conjunction with galvanized steel building panels and wrought zinc roofing systems. ILZRO in cooperation with the lead battery industry has augmented research efforts to improve and increase the efficiency and power density of the lead-acid battery as a source of electrical energy for general use in addition to its primary use in automotive vehicles, particularly in response to demands of environmentalists for a totally nonpolluting vehicle.

A comprehensive study of battery manufacturing process fundamentals, sponsored by ILZRO, identified the conditions for casting calcium-lead grids in top-filled molds, using a reducing gas to prevent loss of calcium by oxidation. Battery manufacturers report that tests by auto companies indicate that maintenance-free, calcium-lead batteries may last 50,000 miles and they require no water and are permanently sealed. They can be placed out of the way to make room under the hood for pollution control devices. ILZRO participated in research directed to designing and constructing a prototype electric delivery truck powered by lead-acid batteries. Road tests indicated that operation of the battery-powered delivery vehicle under typical multistop, limited range and speed conditions was technically feasible. ILZRO also reported the development of lead-plastic composite materials combining light weight, corrosion resistance, and ease of forming suitable for such applications as fuel containers and military packaging.

The lead and zinc industry continued to sponsor extensive research into the medical, biological, and environmental aspects of these metals. A cooperative research study on the effect of airborne lead, the Seven-Cities Survey, was sponsored by the American Petroleum Institute and the Environmental Protection Agency. The data collected in this project disclosed that within the range of air-lead concentrations found in the major U.S. cities, airborne lead has no effect on the blood-lead level of the population. This finding was an important factor in the decision to defer implementation of proposed restrictions on the use of lead in gasoline. An ILZRO-sponsored project to determine the possible role lead plays in biological processes also was begun. The project may provide further conclusive data on the human health aspects of lead.

The NAS also reviewed the scientific knowledge on the biologic effects of lead on human health and welfare and issued an evaluation report[15] to help guide EPA decisions on establishing air-quality criteria. NAS concluded that the average lead content of the air over most major cities apparently has not changed greatly over the last 15 years and that little change in the character and magnitude of the effects of atmospheric lead on biologic systems will likely occur for some years to come. The NAS study also found the transfer of lead from the atmosphere to the soil is directly related to the density of automobile traffic with heavy contamination in cities and major roadways and little evidence of contamination in rural areas attributable to lead alkyls. Similarly, the waters of streams and lakes have about the same concentration of lead today as in 1940. Furthermore, there was no evidence to indicate that the amount of lead in diets of people has changed substantially since 1940.

Lead Industries Association, Inc., reported that a group of 55 electric utilities provided new stimulus to battery-powered electric vehicle production by funding a $1 million research program to purchase 100 on-the-road vehicles for practical testing. The program was sponsored by the Electric Vehicle Council (EVC), an affiliate of the Electric Energy Association, New York. The Battronic Corp. division of Boyerton Auto Body Works, Boyerton, Pa., will build the trucks designed as general purpose multistop work vehicles. The trucks will carry a 1,000-pound payload in a 140-cubic-foot cargo space.

Road tests by Toyo Kogyo Co. (Mazda) of a battery-powered delivery truck disclosed that the vehicle was capable of traveling 54 miles on one charge of its lead-zinc batteries and can attain a maximum speed of 44.5 miles per hour.

Considerable research effort was directed by members of the Battery Council International (BCI) to develop faster charging methods for run-down batteries to meet requirements of electric vehicle manufacturers. The Gel electrolyte battery described by Gould, Inc., is safer for handling than conventional wet-charge and dry-charge batteries because the acid is gelled; it is maintenance-free (never needs water) and able to operate in any position, but its capacity is reduced by the gelled electrolyte.

The Bureau of Mines Metallurgy Research Center at Reno, Nev., reported significant progress in developing a hydrometallurgical process for recovering lead and zinc from flotation concentrates by dissolution with chlorine. Extractions of 99% were obtained in preliminary tests by reaction with aqueous chlorine. Metal ions were recovered from pregnant solution by selective precipitation techniques. Progress also was reported by the Bureau investigators at Rolla, Mo., on developing new technology for the recovery of lead from galena, to replace the present sintering and blast furnace reduction with simpler, nonpolluting metallurgy that permits the recovery of elemental sulfur rather than SO_2. The new technology uses vapor phase techniques and hydrogen reduction; metallurgical recovery of at least 98% was achieved and metallic lead of 99.9% purity was produced. Other Bureau of Mines investigations included strengthening lead-antimony alloys by modified rolling techniques, improving fatigue resistance of lead and lead alloys by surface coatings, and developing lead composites for noise control.

Casting metals	7,281	7,139	Chemicals:		
Collapsible tubes	10,041	4,020	Gasoline antiknock additives	264,240	278,340
Foil	4,417	4,592			
Pipes, traps, and bends	18,174	17,780	Miscellaneous chemicals	401	849
Sheet lead	27,607	23,667			
Solder	70,013	71,289			
Storage batteries:			Total	264,641	279,189
Battery grids, posts, etc.	322,236	347,225			
Battery oxides	357,567	379,367	Miscellaneous uses:		
Terne metal	1,409	504	Annealing	4,068	4,329
Type metal	20,812	19,944	Galvanizing	1,395	1,397
			Lead plating	582	638
Total	1,046,366	1,064,359	Weights and ballast	17,453	21,302
Pigments:			Total	23,498	27,666
White lead	4,731	2,814	Other, unclassified uses	15,751	24,826
Red lead and litharge	61,838	69,799			
			Grand total [2]	1,431,514	1,485,254

[1] Includes lead content of leaded zinc oxide and other pigments.

[2] Includes lead that went directly from scrap to fabricated products.

Table 14.—Lead consumption in the United States, by month

(Short tons)

Month	1971	1972	Month	1971	1972
January	118,676	122,272	August	123,174	127,368
February	113,197	123,671	September	130,568	125,984
March	126,579	132,311	October	127,763	132,241

[e] Estimate. [p] Preliminary. [r] Revised.

[1] In addition to the countries listed, Pakistan, Uganda and Arab Republic of Egypt may produce lead, but available information is inadequate to make reliable estimates of output levels.

[2] Recoverable metal; content of lead in concentrate for exports plus lead content of domestic smelter products (refined lead, antimonial lead, mixed bars, and other unspecified items.)

[3] Recoverable metal.

[4] Recoverable metal; content of lead in concentrate for exports plus lead content of domestic smelter products (refined lead, antimonial lead, and bismuth-lead bars).

[5] For 1970 and 1971, data are for year ending June 30 and represent lead production from Tsumeb Corp., Limited, South-West Africa Co., Limited, and South African Iron and Steel Industrial Corporation, Rosh Pinah mine. For 1972 only, Tsumeb Corp. data is for calendar year 1972. Tsumeb Corp. production for 6 months ending December 1971 was 30,589 short tons.

[6] Year beginning March 21 of that stated.

[7] Content of concentrate.

[8] Contained in lead-copper concentrate.

[e] Estimate. [p] Preliminary. [r] Revised.

[1] Primary except as noted, or where source does not differentiate.

[2] Includes recovery from secondary materials.

[3] Refined from domestic and foreign ores, excludes lead refined from imported base bullion.

[4] Includes primary lead content of antimonial lead.

[5] Lead bullion from imported ores and concentrates.

[6] Year ended June 30 of years 1970 and 1971. Data for 1972 are for fiscal year. Production for last 6 months of 1971 was 36,506 short tons.

[7] Lead in lead bars plus gross weight of antimonial lead; excludes lead in solder.

[8] Year beginning March 21 of year stated.

Lime

By Avery H. Reed[1]

Lime output in 1972 increased 4%, to 20.3 million tons, and set a new annual record. Total value was a record $341.1 million, 10% above 1971.

Santa Rita Mining Co. started up its new plant near Tucson, Ariz. The plant was established to service southern Arizona's copper industry with lime and fluxing stone. The kiln is an 11- by 275-ft rotary which had previously been used at a cement plant. Capacity is 16 tons per hour.

Inland Steel Co. announced plans to construct a 1,200-ton-per-day lime plant at Indiana Harbor, Ind. The plant is to be a Kennedy Van Saun Corp. project to serve the company's new basic oxygen furnace (BOF) steel mill at Indiana Harbor.

Paul Lime Plant, Inc. installed a new 10- by 300-ft rotary kiln at its plant near Douglas, Ariz. to supply lime to copper companies.

At Woodville, Ohio, Woodville Lime & Chemical Co. reopened its plant, which had been shut down for 10 years. A new

[3] Bureau of the Census.

10- by 265-ft kiln was installed. Capacity is 330 tons per day.

Pfizer, Inc. added a seventh kiln at their Gibsonburg, Ohio, plant. Capacity of the new kiln is 130,000 tons per year.

DOMESTIC PRODUCTION

Lime producers sold or used 20.3 million tons, compared with 19.6 million tons in 1971. Sales of lime increased 8%, to 13.4 million tons, and were 2% above the 1969 record. Captive lime used by producers decreased 4% below the 1971 record. Output of refractory dolomite increased 7%, but was 56% below the 1956 record. The num-

[1] Excludes regenerated lime. Includes Puerto Rico.

ber of plants decreased from 188 to 186 and the average output per plant increased from 104,400 tons per year to 109,300 tons.

Six States, Ohio, Missouri, Pennsylvania, Texas, Michigan, and Illinois, accounted for 61% of the total output.

Leading producing companies were Marblehead Lime Co. with four plants in Illinois and one each in Indiana, Michigan, Pennsylvania, and Missouri; Mississippi Lime Co. in Missouri; Allied Chemical Corp. in New York and Louisiana; PPG Industries, Inc. in Ohio and Texas; Bethlehem Steel Corp. with two plants in Pennsylvania and one in New York; Martin-Marietta Chemicals in Ohio and Alabama; United States Gypsum Co. with two plants in Texas and one each in Alabama, Ohio, and Louisiana; Pfizer, Inc. in Ohio, Massachusetts, California, and Connecticut; Warner Co. with two plants in Pennsylvania; and Diamond Shamrock Chemical Co. in Ohio. These 10 companies, operating 30 plants, accounted for 45% of the total lime production.

The seven largest lime plants, each producing more than 400,000 tons per year, accounted for 23% of the total production. There were 36 plants which produced more than 200,000 tons per year and accounted for 65% of the total output.

CONSUMPTION AND USES

Lime was consumed in every State. For total lime, the leading consuming States were Ohio, Pennsylvania, Michigan, Texas, Indiana, and Illinois. These six States, each of which consumed more than 1 million tons, accounted for 58% of the total lime consumed.

Leading quicklime-consuming States were Ohio, Pennsylvania, Michigan, Indiana, and Texas, each of which consumed more than 1 million tons. Combined, these five States accounted for 54% of quicklime consumption.

Texas, Pennsylvania, Ohio, Illinois, Oklahoma, and Louisiana were the leading hydrate consuming States, each of which consumed more than 100,000 tons. These six States accounted for 54% of the hydrate consumed.

[2] Includes Alaska, Maine, New Hampshire, Oklahoma, Puerto Rico, Vermont, Wyoming, and destinations indicated by symbol W.

Lime sold by producers was used for chemicals (80%), construction (11%), refractories (8%), and agriculture (1%).

Captive lime used by producers was 34% of the total, compared with 37% in 1971 and 36% in 1970.

Leading individual uses were basic oxygen steel furnaces, alkalies, water purification, and refractories, which together accounted for 58% of the total consumption, compared with 56% in 1971.

Lime used in agriculture reversed the downward trend of recent years and expanded 72%. Lime used for refractory dolomite also reversed the downward trend and increased 7%. Construction uses continued to expand, increasing 2%. Lime for chemical and industrial use also continued to expand, increasing 9%.

PRICES

The average value of lime sold or used by producers in 1972 was $16.78 per ton, an increase of 6% over the 1971 value of $15.78 per ton.

Values for quicklime ranged from $15.76 for agricultural lime to $16.08 for chemical lime, $16.90 for construction, and $20.52 for refractory dolomite, and averaged $16.35 per ton. Each of these values was higher than in 1971.

Values for hydrated lime ranged from $19.45 for construction lime to $19.66 for chemical lime and $21.32 for agricultural lime, averaging $19.60 per ton.

FOREIGN TRADE

Exports of lime decreased 43%, to 37,659 tons, and were 45% below the 1968 record. Of the total quantity exported, Canada received 68%, Surinam 14%, and Mexico 7%. The remaining 11% went to 35 countries, listed in order as follows: Panama, Jamaica, British Bahamas, Haiti, Indonesia, West Germany, the United Kingdom, Japan, Belgium, British Honduras, Sweden, Nicaragua, Venezuela, Argentina, Ecuador, the Philippines, Leeward and Windward Islands, Denmark, Austria, Brazil, Chile, Honduras, Thailand, New Zealand, Colombia, Australia, the Netherlands Antilles, the Dominican Republic, Iceland, Pacific Trust Islands, India, the Republic of South Africa, Hungary, Italy, and Zambia.

Imports of lime, mainly from Canada, increased to 248,500 tons, 3% above the 1971 record. Small quantities were imported from the Dominican Republic (1,088 tons), Mexico (231 tons), France (102 tons), and West Germany (52 tons).

WORLD REVIEW

Canada.—During 1972 there were 22 active lime plants in Canada: nine in Ontario, four in Quebec, four in Alberta, three in Manitoba, one in British Columbia, and one in New Brunswick. Of the 80 kilns in operation, 55 were vertical, 21 were rotary, 3 were rotary grate, and 1 was vibatory grate. Output in 1972 was 1,606,000 tons.

Companies active in Ontario were Algoma Steel Corp. Ltd., Allied Chemical Canada Ltd., Canadian Gypsum Co. Ltd., Cyanamid of Canada Ltd., Chromasco Corp. Ltd., Domtar Chemicals Ltd., Reiss Lime Co. of Canada Ltd., and The Steel Co. of Canada Ltd.

Active companies in Quebec were Dominion Lime Ltd., Domtar Chemicals Ltd., Gulf Oil Canada Ltd., and Quebec Sugar Refinery. Dominion Lime announced plans for a new 100-ton-per-day kiln.

In Alberta three companies produced lime, Canadian Sugar Factories Ltd., Steel Brothers Canada Ltd., and Summit Lime Works, Ltd. Steel Brothers constructed a second rotary kiln in 1972 which doubled the plant capacity. Steel Brothers Canada Ltd. and The Manitoba Sugar Co. Ltd. were active in Manitoba. Texada Lime, Ltd. built a calcimatic kiln in British Columbia. Havelock Lime Works Ltd. installed a 100-ton rotary kiln at Havelock, New Brunswick.

Germany, West.—West Germany ranked

third in world lime production, accounting for 11% of the world total. Most of the lime was consumed in Germany.

Israel.—Even Vesid, Ltd. announced plans for a 200-ton-per-day rotary kiln to be built at Shfeya.

U.S.S.R.—The U.S.S.R. was the leading lime producing country in the world, accounting for 22% of the world total. The lime was used for construction (51%), iron and steel (25%), chemicals (13%), and sugar (11%).

[e] Estimate. [p] Preliminary. [r] Revised.

[1] Lime is produced in many other countries besides those listed. Zaire, Mexico, Nicaragua, Venezuela and United Kingdom are among the more important countries for which official data are unavailable.

[2] Includes lime for agriculture for 1970, excludes lime for agriculture for 1971 and 1972.

[3] Excludes output by small producers.

[4] Year ending June 30 of that stated.

TECHNOLOGY

Tarmac Roadstone Holdings, Ltd. of England, successfully converted a shaft-type lime kiln to the use of liquid butane.

Air pollutants from a rotary lime kiln are dependent on the stone charged and the fuel used. The gaseous effluent usually consists of water vapor, carbon dioxide, and nitrogen, and may contain sulfur oxides. The particulate emissions usually include flyash, lime dust, limestone dust and tars, and may include unburned coal. The quantity of dust from a lime kiln may range up to 15% of the kiln feed.

New environmental regulations require the abatement of these air pollutants or forced closure of the plant. Present applications use the wet scrubber, fabric filter, or electric precipitator. Alternate methods, which will also control the gaseous emissions, are being studied.

Magnesium

By E. Chin [1]

Production and shipments of magnesium metal by The Dow Chemical Company were 120,823 short tons and 111,185 short tons, respectively, in 1972. Disposal of magnesium from the Government stockpile throughout the year totaled 7,737 tons.

Currently, domestic capacity to produce primary magnesium metal represents 58% of the total world production capacity. With the entry of a fourth U.S. producer of magnesium metal, total domestic production capacity will be 235,000 short tons per year by 1975.

Legislation and Government Programs.—In 1970, the Office of Emergency Preparedness removed magnesium metal from the list of strategic and critical materials, and the stockpile objective for magnesium was abolished. Under authority of Public Laws 90–604, 91–321, and 92–113, the General Services Administration (GSA) continued the disposal of all the magnesium remaining in the national stockpile.

In 1970, GSA sold 14,572 short tons of metal from the Government stockpile, compared with 710 tons in 1971. A total of 7,737 short tons of magnesium was sold during 1972, leaving 89,926 short tons in the stockpile at yearend.

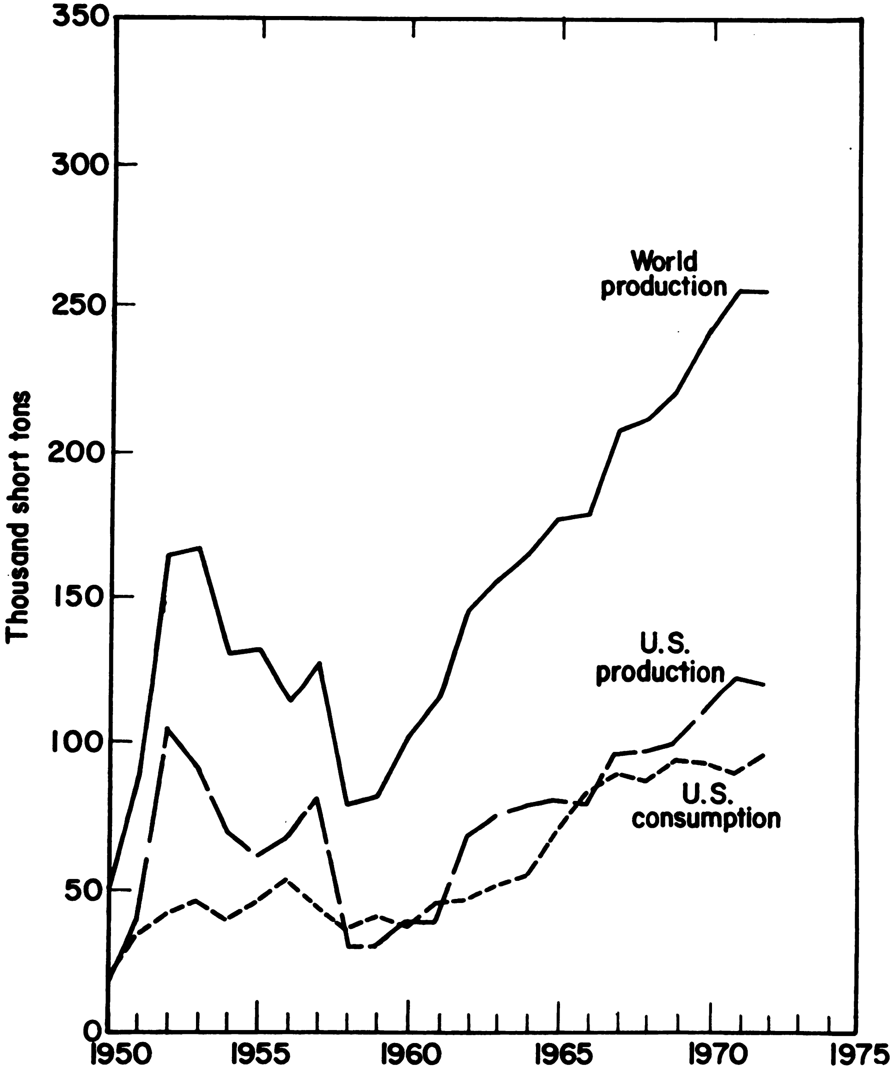

Figure 1.—U.S. and world production and U.S. consumption of primary magnesium.

DOMESTIC PRODUCTION

Production of primary magnesium metal by The Dow Chemical Co. at Freeport, Tex., was 120,823 short tons in 1972. American Magnesium Co. (American Magnesium) at Snyder, Tex., and NL Industries, Inc. (NL), at Rowley, Utah, also produced some metal.

In compliance with an order of the Texas Air Control Board, American Magnesium halted production in mid-1971 to effect improvements in the effluent control systems at its plant. In 1972, American Magnesium was granted a license to use a U.S.S.R.-designed electrolytic cell. Soviet technicians visited the electrolytic plant at Snyder, Tex., to assist American Magnesium's personnel with the operation of the cell, which is reportedly the largest in the Western World. Late in the year, the reduction plant was operated intermittently and some magnesium metal was produced.

Late in 1972, NL initiated operational startup of its magnesium reduction plant, located on the southwestern shore of the Great Salt Lake, near Rowley and Grantsville, Tooele County, Utah. NL's electrolytic plant has a rated annual capacity of 45,000 tons per year of magnesium metal and 70,000 tons of chlorine. Electrical power for NL's project was supplied by the Utah Power and Light Co.

NL's process uses a modified electrolytic cell of the I.G. Farben design and a closed metal circulation system. Raw material source is the brine from the Great Salt Lake which contains approximately 0.7% magnesium, about five times more than sea water. The lake brines are pumped into precipitation ponds where solar evaporation increases the concentration of the magnesium chloride from 2.5% to 30%. From there it is pumped into holding tanks for storage as raw material feed. The storage tanks hold more than a 1-year supply of magnesium chloride for cell feed.

Early in 1972, Great Salt Lake Minerals and Chemicals Corp. (GSL) received $2.975 million from Dow in cancellation payments for the $3 million magnesium chloride facility GSL built at Ogden, Utah. The facility was to supply magnesium chloride for Dow's proposed magnesium plant at Dallesport, Oreg. In 1971, Dow indefinitely delayed the construction of the Dallesport magnesium chloride reduction facility.

The Aluminum Company of America (Alcoa) acquired a license from France's Péchiney Ugine Kuhlmann to use the Magnetherm process for the production of magnesium metal. The magnesium plant, to be situated at Addy, Wash., will use dolomitic limestone deposits in the area for the metal production. The Magnetherm process involves the reduction of calcined dolomite by ferrosilicon at temperatures in excess of 1,500° C. Northwest Alloys, Inc., a newly formed Alcoa subsidiary, will begin construction of the facility in April 1973 with startup targeted for March 1975. Initial capacity will be 24,000 tons per year of magnesium and an ultimate capacity of 40,000 tons per year. The $50 million facility will have a work force of 200 to 250 persons, and will be increased to 300 to 400 persons as capacity is brought up to 40,000 tons per year. The Bonneville Power Administration will supply electricity beginning in October 1974 to the 240-acre Addy site located 50 miles northwest of Spokane. The magnesium and byproduct silicon, two important alloying agents for aluminum, will be used internally by Alcoa.

CONSUMPTION AND USES

Consumption of magnesium in the United States reversed the 1971 decline and rose to almost 100,000 short tons. Magnesium metal is consumed in two broad categories: Structural products such as castings and wrought products, and distributive or sacrificial applications where advantage is taken of the metal's chemical properties. At present, about one-third of consumption is for structural applications while sacrificial uses account for the remaining two-thirds of magnesium consumption.

A wide-ranging series of applications for magnesium were noted in 1972. Archery bow handles, baseball bats, bowling pins, pack frames, snowmobile parts, and staple nailers were among the promising new uses for magnesium die castings. A yttrium-zinc-magnesium base alloy, developed by the Frankford Arsenal, was being used and tested for various helicopter parts. An aluminum-magnesium-steel shield will cap the Centaur booster and Viking spacecraft scheduled to be launched for Mars in 1976.

The use of magnesium and aluminum in U.S. automobiles is expected to increase sharply in the next 5 years, due to the necessity of minimizing the weight of cars. The target for weight reduction per car is about 300 pounds, approximately the weight of mandatory safety and emission control equipment. Some new car models to be introduced in the fall of 1973 will feature magnesium fender extensions as well as decorative items.

The Melmag racing car wheel, designed by Magnesium Elektron, Ltd., won the 1972 Design Award of the International Magnesium Association. The one-piece, magnesium die-cast deck of the Satellite lawnmower, produced for the Parkton Corp. by Paramount Die Casting, Inc. was awarded first prize in the current production category in the First International Magnesium Die Casting Competition.

In sacrificial applications, the area of magnesium growth was expected to be in such uses as the desulfurization of steel and in anodes for the cathodic protection of buried pipelines and storage tanks. Magnesium dry cell batteries for walkie-talkies are a new application for wrought metal, and magnesium continued to be used in water-activated and sea water-activated reserve cell batteries. Retail sales of dry-cell batteries, excluding those for military applications, were expected to reach $400 million in 1973, and the market was estimated to be growing at more than 10% per year. The alkaline-magnesium cell market, the fastest growing segment, was expected to reach $60 million.

PRICES

During 1972, the quoted base price for primary magnesium pig and ingot in 10,000-pound lots, 99.8% magnesium, f.o.b. plant, was 37.25 and 38.00 cents per pound, respectively. This compares with corresponding prices of 36.25 and 37.00 cents per pound, respectively, during 1971.

Depending upon the state of preservation of the metal available from the national stockpile, GSA accepted bids for primary magnesium ranging from 28.25 to 34.75 cents per pound, f.o.b. storage locations. The average price of metal sold by GSA during the year was 32.45 cents per pound.

STOCKS

Producer and consumer stocks of primary magnesium totaled 22,011 tons as of December 31, 1972. Yearend stocks of primary magnesium alloy ingot were 986 short tons. Stocks a year earlier were 13,021 short tons of primary metal and 1,727 short tons of alloy ingot.

Table 4.—Stocks and consumption of new and old magnesium scrap in the United States in 1972

(Short tons)

Item	Stocks Jan. 1 r	Receipts	Consumption			Stocks Dec. 31

FOREIGN TRADE

As in prior years, the United States continued to be a net exporter of magnesium metal in 1972. However, U.S. exports of magnesium metal in all forms, declined from 24,311 short tons, valued at $15.7 million in 1971, to 17,556 tons, valued at $11.7 million in 1972. For the past decade, West Germany was the largest single export destination for U.S. metal. However, in 1972 U.S. exports to West Germany declined sharply, totaling only 859 tons.

Imports by Brazil, Canada, and Japan accounted for 31, 20, and 7%, respectively, of the total U.S. magnesium metal exported. Shipments to France, Italy, Mexico, Switzerland, the United Kingdom, and West Germany collectively totaled 4,157 tons or 24% of total exports. The remaining 3,113 tons were exported to some 20 countries.

Total U.S. imports for consumption of magnesium were 4,479 short tons, valued at $2.6 million in 1972, compared to 3,671 tons, valued at $2.3 million in 1971. Canada, the largest of U.S. sources in 1972, contributed 1,618 tons of the total metal imported. Receipts from West Germany and the Netherlands were, respectively, 1,101 and 513 tons. The remainder of U.S. imports, 1,247 tons, was contributed by 15 other nations.

The duty on unwrought magnesium, other than alloys was 20% ad valorem, and on unwrought magnesium alloy (magnesium content) was 8 cents per pound plus 4% ad valorem. The duty on wrought magnesium metal was 6.5 cents per pound plus 3.5% ad valorem.

WORLD REVIEW

World production of magnesium metal in 1972, excluding two U.S. producers, was 255,995 short tons, an increase of 242 tons over world production in 1971. The United States produced 47% of the world magnesium output, followed by the U.S.S.R. 23%, and Norway 16%. The remaining 14% was by Canada, People's Republic of China, France, Italy, and Japan.

World producers of magnesium with annual capacities, processes, and plant locations are as follows:

Country	Company	Capacity (short tons)	Process	Plant location
Canada	Chromasco Corporation Limited	12,000	Silicothermic	Haley, Ontario.
China, People's Republic of	NA	5,000	do	Ying-kou, Liaoning.
France	Société Générale du Magnésium Péchiney Ugine Kuhlmann S.A. (70 percent). Société des Produits Azotés (SPA) (30 percent).	9,000	do	Marignac.
Italy	Societá Italiana per il Magnesio e Leghe di Magnesio.	7,700	do	Bolzano.
Japan	Furukawa Magnesium Company	7,700	do	Koyama.
	UBE Industries, Ltd	6,600	do	Yamaguchi.
Norway	Heroya Electrokemiske Fabrikker A/S subsidiary of Norsk Hydro-Elektrisk A/S	47,000	I. G. Farbenindustrie	Heroya.
U.S.S.R	NA	50,000	Electrolytic	NA.
United States	American Magnesium Co	80,000	do	Snyder, Tex.
	The Dow Chemical Co	120,000	Dow cells	Freeport, Tex.
	NL Industries, Inc	45,000	Electrolytic	Rowley, Utah.

NA Not avallable.

Australia.—A research group at the University of Tasmania was investigating the feasibility of constructing a sea water magnesium facility in Australia. The main purpose of the study was to determine if all of Australia's magnesium requirements could be satisfied by a sea water magnesium plant.

India.—The Central Electrochemical Research Institute at Karaikudi started production from its magnesium pilot plant rated at 550 pounds of metal per day. A 10,000-ampere cell with a monthly capacity of 1.7 short tons was commissioned. The project was jointly sponsored by the Council of Scientific and Industrial Research and the Tamil Nadu Government. A larger scale plant with an annual capacity of 660 short tons employing the same process was scheduled for construction. The cost of production was estimated to be approximately equivalent to the price of imported magnesium.

The large reserves of magnesite at Salem and the considerable tonnages of sea bitterns to be produced at Tuticorin encouraged the Tamil Nadu Government to finance the project. The Research Institute developed a spray drier with a rated capacity to produce 155 pounds per hour

Table 7.—Magnesium: World production by country

(Short tons)

[e] Estimate. [p] Preliminary. [r] Revised.

[1] The United Kingdom, listed among producers in previous editions, has been deleted because it was determined that the material credited to the United Kingdom subsequent to 1966 is entirely remelt alloy.

[2] Excludes two U.S. producers.

of partially anhydrous magnesium chloride from magnesium chloride solution. The metal production process involves the electrolysis of anhydrous magnesium chloride in a fused salt bath at 700° C.

Japan.—Mitsubishi Chemical Industries Co., Ltd., abandoned its plans to build a small electrolytic magnesium plant in Japan. The original plans had called for an electrolytic plant with an initial capacity of 5,000 tons per year of magnesium.

Netherlands.—Shell Minerals Netherlands NV (Shell) announced that it decided to postpone indefinitely its magnesium chloride project in the Friesland province of the country. Shell stated that it had suitable processing technology for magnesium, but that it was still too costly. Also, world prices for light metals, especially for aluminum, were depressed and that there was no prospect of a recovery in the near future.

The Netherlands Economics Ministry in The Hague said that Shell would not be given the production license it applied for 1½ years ago in view of the company's decision to shelve the project. The award had been delayed a number of times due to local opposition on environment-protection and pollution grounds.

The Economics Ministry added that, in view of the importance of the project for the economic development of the northern provinces of the Netherlands, it intended to set up an independent group to study other possibilities for exploiting the magnesium in the short term. Shell agreed to place the necessary technical information at the group's disposal.

Norway.—The Magnesium Division of Norsk Hydro A/S created a special 20-man technical staff to engage in technical marketing and to develop new applications for magnesium. The technical staff reported potential in the fields of alloying, electroplating, pressure die casting magnesium, and organic synthesis.

U.S.S.R.—The estimated production of magnesium metal in 1972 was 60,000 short tons, a 3,000-ton increase over 1971 production. According to the Soviet weekly ECOTASS, Russian magnesium exports reached 19,900 tons in 1972, a 34% increase compared with the 14,800 tons shipped in 1971.

TECHNOLOGY

The research laboratories of Alcoa developed a process whereby the magnesium content of aluminum scrap is reduced from about 0.5% to 0.1%.[2] Conventional methods to reduce the magnesium content of scrap produced chloride fumes. Alcoa's Fumeless Demagging Process, a pollution-free process, reportedly lowers operating costs and produces 99% pure magnesium chloride, a salable byproduct. The process involves the reaction of magnesium and chlorine by multiple-stage gas-liquid contacting in a closed reactor-settler tank, eliminating wet or dry scrubbers and dust filters. The operating costs are approximately one-third of those for chlorine fluxing and scrubbing systems. The capital cost is estimated at $75,000 for a system to remove magnesium from 24 million pounds per year of alloy scrap. The process is currently being installed at Alcoa's Davenport, Iowa, smelter where it will be used for in-plant wrought alloy scrap.

To prevent molten magnesium from oxidizing on contact with air, the molten metal is presently covered with a mixture of fine potassium and magnesium chloride powder. The Magnesium Research Center at Battelle Memorial Institute announced a $160,000 research program on the fluxless melting of magnesium which may possibly reduce the cost of casting magnesium by 4 cents per pound. Data from laboratory experiments as well as from commercial operations indicate that sulfur hexafluoride (SF_6) was a practical oxidation inhibitor for molten magnesium.[3] The optimum concentration of SF_6 in air for most efficient protection of molten magnesium is 1/10% or less.

Research by Bureau of Mines investigators showed that yields of vanadium in excess of 98% can be achieved by reducing vanadium dichloride with magnesium.[4] The resultant vanadium metal product has a purity greater than 99.8%. The high efficiencies in the individual process steps indicated that vanadium produced with magnesium as the reductant has an excellent potential from an economic standpoint.

[3] Hanawalt, J. D. Practical Protective Atmospheres for Molten Magnesium. Metals Engineering Quarterly, November 1972.

Other investigations by the Bureau of Mines demonstrated that nitrogen was an effective medium for quenching magnesium vapor produced in the carbothermic process.[5] Contrary to prior belief, the formation of magnesium nitride was not a major problem. For the carbothermic process to be cost competitive with the electrolytic process, large volumes of the quenching agent must be available at low cost. Nitrogen is available in abundant supply, and as a byproduct of oxygen production in steel and other metallurgical plants, should be relatively inexpensive.

According to the American Cast Iron Pipe Company (Acipco), Birmingham, Ala., magnesium-impregnated coke (Mag-Coke) is an effective desulfurizing agent for steel.[6] Acipco estimated that 1 pound of Mag-Coke would remove 0.018% of sulfur per ton of iron; the removal of 0.01% of sulfur per ton of iron would cost 25 to 30 cents. Spokesmen for several steel producers confirmed experimenting with Mag-Coke. Republic Steel Corp. reported that the use of Mag-Coke was beyond the research stage and was being used in regular iron production at its Warren, Ohio, and Gadsden, Ala., facilities.

Magnesium Compounds

By E. Chin [1]

World production of magnesite in 1972, excluding production in the United States, was estimated to be 9,764,474 short tons, a decrease of 2% from world production in 1971. Magnesite production in Austria, Czechoslovakia, North Korea, People's Republic of China, and the U.S.S.R. accounted for 71% of the total world output. The increase in the world production capacity for recovering magnesia from sea water, however, continued to exert competitive pressure on producers of magnesite.

Refractory magnesia and caustic-calcined and specified magnesias sold or used by domestic producers in 1972 were 9% above that sold or used in 1971. The value of domestic shipments of magnesias rose 10% to $76,187,000.

U.S. imports for consumption of processed magnesite were 133,734 tons; imports from Greece accounted for 58% of the 1972 total. Exports of magnesite and magnesia were 61,196 tons in 1972, and as in the 1970–71 period were primarily to Canada.

[2] Caustic-calcined magnesia only.

DOMESTIC PRODUCTION

In 1972, 909,428 short tons of magnesium hydroxide was produced from sea water and well brines. Output was by Barcroft Co., The Dow Chemical Company, Kaiser Aluminum & Chemical Corp., Merck & Co., Inc., and Michigan Chemical Corp. Most of the magnesium hydroxide was used in the production of magnesia for basic refractories. Producers of refractory magnesia were Basic Inc., Basic Magnesia, Inc., Corchem, Inc., A. P. Green Refractories, Co., Harbison-Walker Refractories Co., Kaiser Aluminum & Chemical Corp., Martin-Marietta Chemicals (formerly Standard Lime and Refractories Co.), and Northwest Magnesite Co. Total production of refractory magnesia in 1972 was 575,707 tons.

---

[1] Physical scientist, Division of Nonferrous Metals.

During the year, 189, 889 tons of caustic-calcined magnesia was produced by Basic Inc., Basic Magnesia, Inc., The Dow Chemical Company, Kaiser Aluminum & Chemical Corp., Martin-Marietta Chemicals, and Michigan Chemical Corp. Six companies produced 11,091 tons of specified magnesias.

Magnesium chloride was produced by American Magnesium Co., J. T. Baker Chemical Co., The Dow Chemical Co., FMC Corp., Great Salt Lake Minerals & Chemicals Corp., Kaiser Aluminum & Chemical Corp., Mallinckrodt Chemical Works, and NL Industries, Inc. Most of the magnesium chloride production was used for magnesium metal cell feed.

Production of magnesium sulfate was reported by four companies. Producers of other magnesium compounds were J. T. Baker Chemical Co., Mallinckrodt Chemical Works, Merck & Co., Inc., and Waverly Chemical Co., Inc.

Basic Magnesia, Inc., completed an expansion program at its sea water magnesia plant in Port St. Joe, Fla., with the installation of special material processing equipment, increased bagging capacity, and new bulk loading facilities for both trucks and railroad cars. Improvements were also made in the reaction system controls, which were designed to yield more uniform and higher quality oxides.

Table 2.—Dead-burned dolomite sold or used by producers in the United States

(Thousand short tons and thousand dollars)

Year	Sales of domestic product	
	Quantity	Value
1968	1,833	31,627
1969	1,866	33,580
1970	1,373	25,740
1971	1,020	19,128
1972	1,125	21,097

Domestic producers of magnesium compounds by raw material source, location, and annual capacity are listed as follows:

Raw material source and producing company	Location	Capacity (short tons MgO equivalent)
Magnesite:		
Basic Inc	Gabbs, Nev	150,000
Lake brines:		
Great Salt Lake Minerals & Chemicals Corp	Ogden, Utah	100,000
NL Industries, Inc	Rowley, Utah	75,000
Well brines:		
American Magnesium Co	Snyder, Tex	50,000
The Dow Chemical Co	Ludington, Mich	250,000
Martin Marietta Chemicals	Manistee, Mich	100,000
Michigan Chemical Corp	St. Louis, Mich	25,000
Morton Chemical Co	Manistee, Mich	5,000
Sea water:		
Basic Magnesia, Inc	Port St. Joe, Fla	100,000
Barcroft Co	Lewes, Del	5,000
Corchem, Inc	Pascagoula, Miss	40,000
The Dow Chemical Co	Freeport, Tex	250,000
FMC Corp	Chula Vista, Calif	5,000
Kaiser Aluminum & Chemical Corp	Moss Landing, Calif	150,000
Merck & Co., Inc	South San Francisco, Calif	5,000
Northwest Magnesite Co	Cape May, N.J	100,000
Total		1,410,000

CONSUMPTION AND USES

In 1972, 696,102 tons of magnesia was used in the production of basic refractories, compared with 626,513 tons in 1971. Consumption of caustic-calcined magnesia for uses other than the production of refractory magnesia included chemical processing, animal feed, pulp and paper, rayon, and sugar. Specified magnesias were used primarily in electrical, medicinal, and rubber applications.

Olivine was consumed as a molding sand in various foundries and as a metallurgical flux in the smelting of steel.

Magnesium chloride was used as an antifreeze agent and in the processing of molasses. Magnesium carbonate was consumed in the production of cosmetics and pharmaceuticals.

Table 3.—Magnesium compounds shipped and used in the United States

Year and product	Plants	Shipped and used	
		Quantity (short tons)	Value (thousands)
1971			
Caustic-calcined [1] and specified (U.S.P. and technical) magnesias	12	[r] 126,722	[r] $18,621
Refractory magnesia [2]	9	[r] 626,518	[r] 50,359
Magnesium hydroxide (100 percent $Mg(OH)_2$) [1]	9	71,366	[r] 2,030
Magnesium chloride [3]	8	575,674	[r] 35,744
Precipitated magnesium carbonate [1]	6	5,510	[r] 1,251
1972			
Caustic-calcined [1] and specified (U.S.P. and technical) magnesias	11	128,260	$15,856
Refractory magnesia [2]	8	696,102	60,331
Magnesium hydroxide (100 percent $Mg(OH)_2$) [1]	10	66,671	2,454

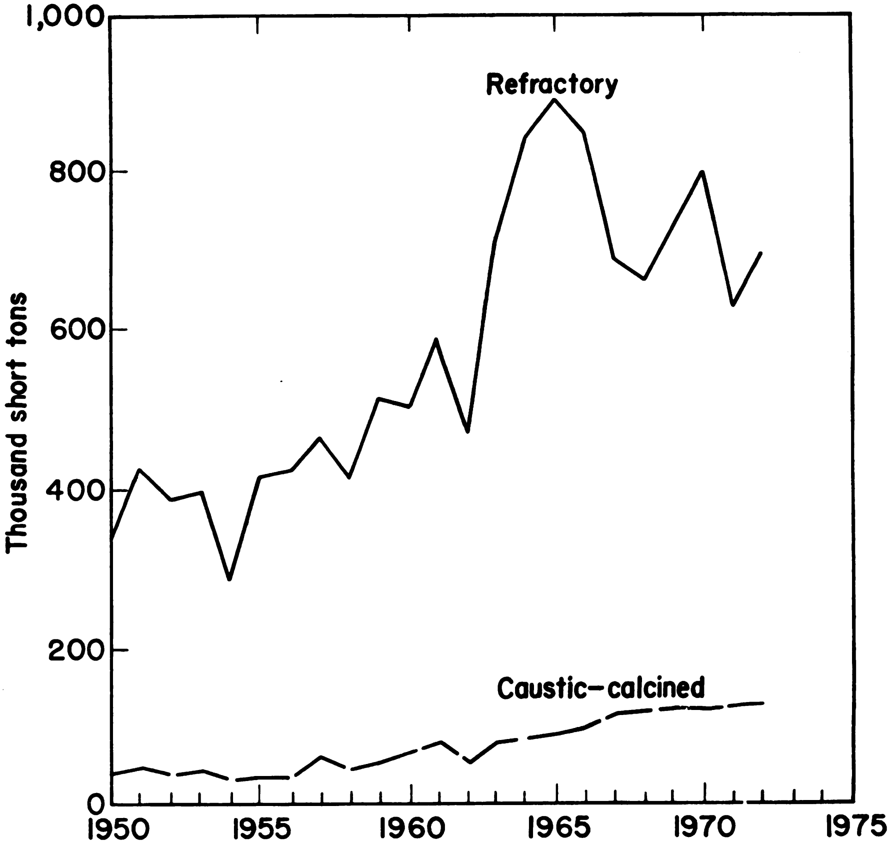

Figure 1.—Consumption and shipments of magnesia in the United States.

PRICES

Prices for magnesia, calcined, technical, heavy, 85% and 90% (bags, carlot, f.o.b. Luning, Nev.) were quoted during the year at $50 and $60 per short ton, respectively according to the Chemical Marketing Reporter. Magnesia, technical, synthetic rubber-grade, neoprene-grade, light, was quoted with no change from the 1971 price at $0.24 per pound (bags, carlot, freight-equalized).

Prices throughout the year for magnesium carbonate, technical (bags, carlot, freight-equalized), remained the same as in 1971 at $0.16 per pound; for truckload quantities prices remained at $0.18 to $0.185 per pound. During the year the price for magnesium hydroxide, NF, powder (drums, carlot, and truckload, works) ranged from $0.21 to $0.295 per pound. Magnesium chloride, hydrous, 99%, flakes, bags, carlot, works, was quoted at $72.80 per ton. The price for magnesium lauryl sulfate, tanks, freight-allowed, remained the same as in 1971 at $0.175 per pound.

FOREIGN TRADE

Exports of dead-burned magnesite and magnesia in 1972 totaled 54,159 tons compared with 53,448 tons in 1971. Exports to Canada in 1972 were 51,694 tons, 21%

higher than in 1971. However, shipments to Mexico, Peru, and Spain in 1972 were substantially lower than those of 1971.

Exports of magnesite, including crude, caustic-calcined, lump or ground, decreased slightly from exports in 1971. Deliveries to West Germany, Canada, Italy, the United Kingdom, and Australia accounted for over 50% of the exports in this class.

Imports for consumption of lump or ground caustic-calcined magnesia decreased 10% in 1972 to 10,376 tons. Imports in this class were principally from India and Turkey.

Imports of dead-burned and grain magnesia and periclase containing a maximum of 4% lime increased 10% to 127,776 tons in 1972. Imports for the same class of material but containing over 4% lime decreased from 13,146 tons in 1971 to 5,958 tons in 1972. Total imports of magnesite increased 4% over those in 1971 to 133,734 tons.

Imports of unspecified magnesium chloride, magnesium sulfate, and magnesium salts and compounds decreased substantially in 1972 compared to imports in these classes in 1971. Imports of precipitated magnesium carbonate and magnesium oxide increased slightly over those in 1971.

The tariff on various magnesium compounds was as follows:

Item	1971	1972
Magnesite:		
Crude____________per ton__	$3.15	$2.62
Caustic-calcined____do____	$6.30	$5.25
Magnesium carbonate:		
Precipitated cents per pound__	0.25	0.25
Not precipitated-% valorem_______________	5%	4%
Magnesium chloride:		
Anhydrous cents per pound__	.6	.5
Other_____________do____	.25	.21
Magnesium oxide:		
Calcined magnesia__do____	1.2	1
Magnesium sulfate:		
Epsom salts________do____	.225	.187

WORLD REVIEW

Germany, West.—Magnesital-Feuerfest G.m.b.H. initiated construction of its $10 million refractory plant at Oberhausen in the Duisburg area of the Ruhr District. Magnesital-Feuerfest is a joint venture of Dresser Industries, Inc., and Martin & Pagenstecher G.m.b.H., a West German refractories producer. The plant is being built in two phases. The first phase, which calls for the manufacture of high-alumina specialty refractories, is expected to be completed in early 1973. The second phase, for the manufacture of high-quality magnesia refractories used primarily in basic oxygen steelmaking processes, is scheduled to be completed and in operation by December 1973.

Greece.—Société Financière de Grèce (Scalistiri), the largest producer of magnesite in Greece, completed construction of a new loading jetty at Mantoudi, Northern Euboea. With the new jetty, magnesite can be loaded at a rate of 1,000 tons per hour. Other additions such as new silos and a belt conveyor were planned by mid-1973.

India.—Almora Magnesite Ltd. was installing a magnesite processing plant near Almora, Uttar Pradesh. Expected completion date for the construction was the fall of 1973. The plant was expected to produce 100,000 tons of dead-burned magnesite per year. Almora was owned 51% by the UP State Industrial Corp. and 49% by Belpahar Refractories Ltd.

Italy.—Compagnia Generale de Magnesio S.p.A. continued the construction of its 60,000 ton per year sea water magnesia plant near Syracuse, Sicily. Construction of the plant began in August 1971, and at the end of 1972 was nearing completion. Initial production of chemical and refractory magnesia was scheduled for late 1973. High-purity limestone deposits are available at the site and will probably permit an increase of the magnesium oxide content of the magnesia produced at the plant to over 98%.

Netherlands.—Shell Internationale Petroleum Maatschaapij installed a high-pressure water heater at its magnesium salt recovery pilot plant on the Friesian coast. Although fitted with an air atomizing burner for use with oil, the dual fuel heater was fired on natural gas and can handle a water flow of 66,000 pounds per hour.

Tanzania.—The National Development Corp. (NDC) of the Tanzanian Government planned to invest between $280,000 and $344,000 to revive and expand magnesite mining near Samé. This mine was formerly operated by the Tanganyika Magnesite Mines, Ltd. The NDC expected to establish a 24,000-ton-per-year magnesite plant by 1974 and to continue operations for 15 to 20 years on the basis of reserves which have been estimated to be between 1 million and 4 million tons.

United Kingdom.—Steetley Co., Ltd., commissioned a new plant at its Hartlepool works for the production of chemical-grade magnesia. The new plant included a gas-fired, multiple-hearth furnace equipped with special burners designed by Steetley's Central Research Laboratories. The design and instrumentation of the furnace reportedly allowed close control of burning conditions, which permitted a high degree of flexibility in achieving precise physical and chemical specifications, tailored to meet customer requirements.

Yugoslavia.—The state-owned refractory materials producing complex, Magnohrom, announced a $30 million expansion and modernization program of its mining and manufacturing plants at Kraljevo. The expansion program, to be completed by 1975, was expected to increase the present production of 100,000 tons of magnesite brick to 160,000 tons per year, and to increase the production of refractory materials for the steel industry from 4,000 tons to 40,000 tons per year. Plans for the country's first magnesium metal producing facilities were included in the project.

Total			2,220,000

NA Not available.
[1] Under construction.
[2] Sea water production facilities appear in tabulation shown in "Domestic Production" section of this chapter.

TECHNOLOGY

The Philadelphia Electric Company is installing a prototype system to absorb sulfur dioxide from flue gas with magnesium oxide.[2] The system will be in operation in late 1973 and will be the first of its kind installed on a coal-fired unit. The total cost of the facilities will be approximately $15 million.

The Potomac Electric Power Company planned to install a prototype system also to absorb sulfur dioxide from flue gas with magnesium oxide using a process developed by Chemical Construction Company and Basic Chemicals of Cleveland.[3] This plant will not probably be in operation before 1975. The approximate cost of the facilities will be about $6 million.

New methods to beneficiate domestic olivine for foundry sand applications were investigated.[4] A disadvantage of calcining olivine in conventional rotary kiln or fluid-type calciners is partial oxidation of ferrous oxide, which is undesirable in foundry sands. A laboratory tube-type furnace, making use of the free-flowing properties of olivine sand, was designed for continuous calcining. Utilizing this technique, high-quality foundry sand could be produced from olivine by calcining under nonoxidizing conditions.

A report on the refractory magnesia industry in Canada was published by the Mines Branch of the Department of Energy, Mines, and Resources.[5] The review included information on the occurrence of magnesite, current commercial exploitation of magnesite, and sea water magnesia in Canada. An article was published summarizing the development work leading to the analysis of periclase products by atomic absorption.[6] Test results showed that agreement between atomic absorption and wet chemical methods for calcium oxide, silica, iron and alumina were good. It was concluded that atomic absorption methods were suitable for quality control analyses of periclase grain containing greater than 95% MgO.

Manganese

By Gilbert L. DeHuff[1]

There was no actual production of manganese ore, concentrate, or nodules, containing 35% or more manganese, in the United States in 1972, but a small quantity of manganese nodules continued to be shipped from stocks. Imports of managanese ferroalloys and metal were at a high rate, and domestic producers continued to be faced with the problems of pollution control and adequate availability of power. Plans were underway for substantial new capacity for production of electrolytic manganese metal in the Republic of South Africa.

Imports for consumption	203,212	307,891	290,946	242,778	348,539
Consumption	1,016,559	1,071,042	1,000,611	899,011	967,968

Legislation and Government Programs.—Under the provisions of the Strategic and Critical Materials Stock Piling Act, as amended (Public Law 520, 79th Congress) the Office of Emergency Preparedness redetermined the following manganese items to be strategic and critical: Natural battery manganese ore, battery-grade synthetic manganese dioxide, type A chemical-grade manganese ore, type B chemical-grade manganese ore, metallurgical manganese ore, high-carbon ferromanganese, medium-carbon ferromanganese, low-carbon ferromanganese, silicomanganese, and electrolytic manganese metal.

Sales of surplus metallurgical ore in calendar year 1972 totaled 1,243,744 short dry tons. These sales were on a negotiated basis with deliveries limited. Sales of surplus synthetic manganese dioxide in the calendar year were 1,278 short dry tons, all on a competitive sealed-bid basis. No acceptable bids were received in response to a General Services Administration (GSA) offering of surplus natural battery-grade ore, or to its offerings of surplus chemical-grade ore, types A or B.

Manganese stockpile inventory changes in the calendar year consisted of the following:Metallurgical ore, stockpile grade, decreased 490,705 short tons to 7,672,536 tons; metallurgical ore, non-stockpile grade, decreased 2,800 tons to 1,389,771 tons; synthetic dioxide decreased 2,619 tons to 17,019 tons; and stockpile-grade natural battery ore decreased 45 tons to 253,451 tons.

---

[1] Supervisory physical scientist, Division of Ferrous Metals.

DOMESTIC PRODUCTION

Except for a small quantity of metallurgical oxide nodules shipped from stocks by The Anaconda Company, and made several years ago from Montana carbonate ore, there was neither production nor shipment of manganese ore, concentrates, or nodules in the United States in 1972.

Ferruginous manganese ores or concentrates containing 10% to 35% manganese were produced and shipped from New Mexico, and shipments continued from the Cuyuna Range of Minnesota. Manganiferous iron ore containing 5% to 10% manganese was neither produced nor shipped in either 1972 or 1971. Manganiferous zinc residuum continued to be produced from New Jersey zinc ores.

Table 2.—Manganese and manganiferous ore shipped[1] in the United States, by State

(Short tons)

Utah	112	37	--	--
Total	198,334	26,546	147,161	18,727
Manganiferous iron ore (5% to 10% Mn, natural)	--	--	--	--
Total manganiferous ore	198,334	26,546	147,161	18,727
Value manganese and manganiferous ore	$1,468,000	--	$1,040,000	--

[1] Shipments are used as the measure of manganese production for compiling U.S. mineral production value. They are taken at the point at which the material is considered to be in marketable form for the consumer. Besides direct shipping ore, they include, without duplication, concentrate and nodules made from domestic ores.

CONSUMPTION, USES, AND STOCKS

In the production of raw steel (ingots, continous- or pressure-cast blooms, billets, slabs, etc., and including steel castings), consumption of manganese as ferroalloys, metal, and direct-charged ore was 12.6 pounds per short ton of raw steel produced. Of this total, 11.0 pounds was ferromanganese; 1.2 pounds, silicomanganese; 0.05 pound, spiegeleisen; 0.25 pound, manganese metal; and 0.1 pound, manganese ore. The comparable 1971 total, on the same basis, was 13.0 pounds with ferromanganese at 11.2, silicomanganese at 1.3, spiegeleisen at 0.05, metal at 0.25, and ore at 0.2. It should perhaps be observed that, in addition to the above consumption of manganese in 1972, there was consumed per short ton of raw steel produced approximately 1.2 pounds of manganese contained in manganese ore used in making pig iron. In 1971, the quantity was approximately 1.0 pound. This increase in the use of manganese ore (containing more than 35% manganese) as blast furnace feed has been apparent since 1969.

Manganese ferroalloy producers proceeded with their air and water pollution control programs, completion of which will tend to aggravate already existing problems of adequate power supply.

Electrolytic Manganese and Manganese Metal.—All of the manganese metal produced in the United States was electrolytic manganese metal, and it is certain that virtually all of that imported was electrolytic metal. Virtually all of the metal consumed was electrolytic metal, but it is possible that some low-carbon ferromanganese, and possibly some manganese-aluminum additives, may have been erroneously reported by consumers as manganese metal. Production of electrolytic metal in 1972 was 23,200 short tons, compared with 20,475 tons in 1971, and was by the same

[1] Virtually all electrolytic.

three companies: Foote Mineral Co., New Johnsonville, Tenn.; Kerr-McGee Chemical Corp., Hamilton, (Aberdeen), Miss.; and Union Carbide Corp., Marietta, Ohio.

Ferromanganese.—Bethlehem Steel Co. and U.S. Steel Corp. continued to be the only domestic ferromanganese producers using blast furnaces: Bethlehem at Johnstown, Pa.; U.S. Steel in the Pittsburgh district at Clairton and McKeesport, Pa. Electric furnaces were used to produce ferromanganese by the same 6 companies in the same 10 plants as in 1971: Airco Alloys and Carbide Div., Airco, Inc., Calvert City, Ky., and Theodore (Mobile), Ala.; Chromium Mining & Smelting Corp., Woodstock (Memphis), Tenn.; Ohio Ferro-Alloys Corp., Philo, Ohio; Roane Electric Furnace Division of Woodward Corp., a Division of Mead Corp., Rockwood, Tenn.; Tenn-Tex Alloy Corporation of Houston, Houston, Tex.; and Union Carbide Corp., Ferroalloys Div., Alloy, W. Va., Ashtabula and Marietta, Ohio, and Portland, Oreg. Fused salt electrolysis continued to be used by Chemetals Division, Diamond Shamrock Chemical Co., Kingwood, W. Va., to make low-carbon ferromanganese sold under the trade name of Massive Manganese. U.S. shipments of ferromanganese totaled 727,000 short tons, compared with 800,000 tons in 1971.

Silicomanganese.—Production of silicomanganese in the United States was 153,000 short tons, compared with 165,000 tons in 1971. Shipments from furnaces totaled 146,000 tons, compared with 144,000 tons in 1971. In 1972, 7 companies utilized 11 plants to make silicomanganese: Airco Alloys and Carbide Div., Airco, Inc., Calvert City, Ky., and Theodore (Mobile), Ala.; Chromium Mining & Smelting Corp., Woodstock (Memphis), Tenn.; Interlake Inc., Beverly, Ohio; Ohio Ferro-Alloys Corp., Philo, Ohio; Roane Electric Furnace Division of Woodward Corp., a Division of Mead Corp., Rockwood, Tenn.; Tenn-Tex Alloy Corporation of Houston, Houston, Tex.; and Union Carbide Corp., Alloy, W. Va., Ashtabula and Marietta, Ohio, and Portland, Oreg. Consumption of silicomanganese was 12.8% that of ferromanganese, compared with 13.7% in 1971. This continues a steady drop from the recorded high of 18.5% in 1965. Because much of the use of silicomanganese has been for blocking (immediate stoppage of oxidizing action) the open-hearth heat, and blocking is not practiced with the basic oxygen furnace (BOF), this decrease in the ratio of silicomanganese consumption to ferromanganese consumption can probably be attributed in large part to the steadily increasing displacement of the open-hearth by the BOF.

Spiegeleisen.—The New Jersey Zinc Co. continued to produce spiegeleisen solely by electric furnaces at Palmerton, Pa.

Table 5.—Ferromanganese produced in the United States and manganese ore [1] consumed in its manufacture

Year	Ferromanganese produced			Manganese ore [1] consumed (short tons)		
	Gross weight (short tons)	Manganese content		Gross weight [2]		Per ton of ferromanganese [3] made
		Percent	Short tons	Foreign	Domestic

Other or unidentified	69,035	--
Total	1,922,103	48

[1] From U.S. Government surplus stockpile disposals, except for possibly a small tonnage of domestic ore.

Pig Iron.—A total of 434,000 short tons of manganese-bearing ores containing over 5% manganese (natural) was consumed in the production of pig iron (or its equivalent hot metal). Domestic sources supplied 244,000 tons, of which 219,000 tons was manganiferous iron ore containing 5% to 10% manganese, 25,000 tons was ferruginous manganese ore containing 10% to 35% manganese, and 900 tons contained more than 35% manganese. Foreign sources supplied 190,000 tons, of which 5,000 tons was manganiferous iron ore, and 185,000 tons contained more than 35% manganese.

Battery and Miscellaneous Industries.—The ore reported in table 3 includes that consumed in making synthetic manganese dioxide by either electrolytic or chemical means, but it does not include consumption of the synthetic dioxide. Although some synthetic dioxide is used for chemical purposes, most of it is used in the manufacture of dry cell batteries, particularly for the manganese-alkaline battery, premium or heavy-duty Leclanché cells, and as a blend with natural ore in the ordinary Leclanché (manganese dioxide-ammonium chloride-zinc) cell.

The domestic ore and much of the foreign ore used for chemical and miscellaneous purposes did not meet national stockpile specification P–81–R for chemical-grade ore.

In October, C-E Minerals, a division of Combustion Engineering, Inc., closed its Lynchburg, Va., manganese ore grinding plant. The product was used largely for the manufacture of face brick. The equipment was transferred to the Camden, N.J., plant where similar operations continued to be conducted. The company's Brownsville, Tex., and Wilmington, Del., plants also continued to grind imported manganese ores for the same purpose.

PRICES

Manganese Ore.—All manganese ore prices are negotiated, dependent in part on the characteristics and quantity of ore offered, delivery terms, and fluctuating ocean shipping rates. In March, the American Metal Market dropped its price quotation for manganese ore containing 46% to 48% manganese from 59 to 63 cents, nominal, to 58 to 61 cents, nominal, per long ton unit, c.i.f. eastern seaboard and Gulf ports. The quotation for ore containing 48% to 50% manganese was lowered at the same time from 63 to 68 cents, nominal, to 61 to 64 cents, nominal, same basis. Both of the new quotations were maintained for the remainder of the year.

Manganese Alloys.—The domestic producer price for standard high-carbon ferromanganese having a minimum manganese content of 78% remained at $190 per long ton, f.o.b. producer plant or shipping point. Contract sales in quantity apparently were at lower prices to be competitive with imported alloy. Metals Week continued to quote the 74% to 76% manganese grade of imported standard high-carbon ferromanganese at $176 to $178 per long ton of alloy, delivered in Pittsburgh or Chicago, until April. Stating that few consumers continue to use that grade, the paper changed the quotation then to $178 to $180 for standard alloy containing 78% manganese.

Manganese Metal.—The price of standard electrolytic manganese metal again remained unchanged for another full year at 33.25 cents per pound, f.o.b. producer plant, for shipments of 30,000 pounds or more.

FOREIGN TRADE

Exports of ferromanganese were 6,842 short tons valued at $1,511,864, compared with 4,526 tons valued at $1,204,819 in 1971. Of the 1972 total, Canada took 2,956 tons; Sweden, 2,392 tons; Mexico, 1,322 tons; Colombia, 65 tons; France, 51 tons; and small quantities went to each of nine other countries. Exports classified as "manganese and manganese alloys, wrought or unwrought, and waste and scrap" totaled 1,504 tons valued at $1,020,743 in 1972, and 1,203 tons valued at $911,785 in 1971. This classification includes electrolytic manganese metal and manganese-copper alloys, but it does not include ferromanganese. Exports of ore and concentrate containing more than 10% manganese totaled 25,108 short tons at a value of $3,137,104, compared with 55,413 tons at $2,683,070 in 1971. The 1972 exports were believed to consist almost entirely of imported manganese dioxide ore exported after grinding, blending, or otherwise classifying.

The average grade of imported manganese ore was 49% manganese in both 1972 and 1971. More than half of the total continued to come from Gabon and Brazil. There were no imports of manganiferous ores containing more than 10% but less than 35% manganese.

Ferromanganese imports for consumption were the highest on record. However, a good portion of the 1972 total came from foreign companies in which United States producers or consumers have substantial interest. Silicomanganese imports for consumption totaled 38,674 short tons containing 25,901 tons of manganese. Sources and tonnage (gross weight) were as follows: Norway, 26,801; Mexico, 4,364; Spain, 2,536; Yugoslavia, 2,162; Japan, 1,653; Sweden, 551; France, 336; and West Germany, 271. Imports for consumption classified as unwrought manganese metal, except alloys, and waste and scrap of such metal, totaled 4,121 short tons, compared with 2,870 tons in 1971. Of the 1972 quantity, 2,375 tons came from Japan, 1,639 tons from the Republic of South Africa, 105 tons from the Netherlands, and 2 tons from Canada. A small quantity, 5 pounds having a value of $117 per pound, came from Switzerland.

Imports for consumption classified as "manganese compounds, other" totaled 7,937 short tons in 1972, compared with 2,942 tons in 1971. The sources, gross weights, and values per pound in 1972 were as follows: Japan, 4,126 tons (17.5 cents); Morocco, 3,307 tons (1.7 cents); the United Kingdom, 279 (6.9 cents); Belgium-Luxembourg, 218 tons (16.0 cents); the Republic of South Africa, 5 tons (6.7 cents); and West Germany, 2 tons (82 cents). The imports from Japan and Belgium-Luxembourg appear to have consisted largely, if not entirely, of synthetic manganese dioxide.

Table 7.—U.S. imports[1] of manganese ore (35% or more Mn), by country

Country	1971			1972		
	Gross weight (short tons)	Mn content (short tons)	Value (thousands)	Gross weight (short tons)	Mn content (short tons)	Value (thousands)
Angola[2]	56,721	27,603	$982	35,570	17,160	$1,244

Total	1,914,264	938,122	42,184	[3] 1,620,252	792,695	34,315

[1] Quantities for general imports and imports for consumption were identical.
[2] Part or all of the ore reported to have come from Angola in 1971 and 1972 is believed to have originated in Gabon.
[3] It appears that up to 225,000 additional tons (gross weight) may have come from Brazil in 1972.
[4] Less than ½ unit.
[5] Actually from Gabon.
[6] In addition, in 1971, some imports reported as Angola may have originated in Gabon. In addition, in 1972 Gabon imports reported as Congo (Brazzaville) were approximately 35,000 tons (gross weight), Gabon imports reported as Zaire were approximately 130,000 tons (gross weight), and some or all of the imports reported as Angola probably originated in Gabon.
[7] In 1972, actual imports originating in Zaire were approximately 150,000 tons (gross weight); see footnote 6.

[1] Less than ½ unit.

Tariffs.—The Rate 1 duty on manganese ore, applicable to most nations, continued to be suspended throughout the year. If effective, it would have been 0.12 cent per pound of contained manganese, the last of the five annual GATT (General Agreement on Tariffs and Trade) reductions effected by Presidential Proclamation 3822 of December 16, 1967. Ore from the U.S.S.R., the People's Republic of China, and certain other specified Communist countries, continued to be subject to the statutory rate of 1 cent per pound of contained manganese.

WORLD REVIEW

Interest in the prospects for exploitation of deepsea manganese nodules continued to develop rapidly in spite of the uncertainties of the legal problems of ownership, mining rights, etc. Many firms and Governments were active, either directly or indirectly. Particularly active were West German and Japanese interests in association with a variety of firms of U.S. and other nationalities. Deepsea Ventures, Inc., Hughes Tool Co., and Kennecott Copper Co. proceeded on their own and were reported to be well advanced with their plans. In probably all cases, manganese has been abandoned as the prime objective in favor of one or more of the associated nickel, cobalt, or copper, the manganese being relegated to byproduct status to assist in the costs, or in some cases to waste. International Nickel and Société Le Nickel were both active, either on their own or as part of a consortium. The question of the environmental effects of deepsea mining received attention with some inconclusive indications that it could be beneficial. The legal aspects were under study by the United Nations as well as elsewhere.

[e] Estimate. [p] Preliminary. [r] Revised.

[1] In addition to the countries listed, Cuba and South-West Africa also produce manganese ore but information is inadequate to make reliable estimate of output levels. Low grade ore not included in the table has been reported as follows in short tons: Czechoslovakia (about 17% Mn) 1970—95,000; 1971—53,000; 1972—[e] 44,000; Romania (about 22% Mn) about 140,000 in each year; Republic of South Africa (15–30% Mn, in addition to material listed in table) 1970—412,264; 1971—200,220; 1972—112,058.

[2] Estimated on the basis of reported contained manganese.

[3] Exports.

[4] Grade unreported. Source: The National Economy of the U.S.S.R., Central Statistical Administration, Moscow.

[5] Of total 1972 output, 42.4% graded from 35% to 54% Mn. (Comparable 1970 and 1971 production breakdown not available; export figures give 43% and 33% respectively.)

[6] Iranian calendar year beginning March 21, of year stated; all figures apparently are mine run ore.

Angola.—No manganiferous iron ore was produced in 1972. Reported manganese ore production for 1971 was from the mines of Companhia do Manganês de Angola. Exports have been chiefly to Japan but totaled only 12,400 short tons in 1971 compared with 22,600 tons in 1970.

Argentina.—Decree 8203, published in November 1972, restricts manganese ore imports, establishes guidelines for the sale of manganese ore in Argentina, and fixes the prices to be charged. The purpose is to assure a market for all domestically produced manganese ore, which has had to compete since 1970 with Brazilian ore under LAFTA (Latin American Free Trade Association) accords. Because most Argentine mines are small, operate with little benefit of technology, and generally mine ore of poor quality, the costs are high. The decree gives the Ministry of Industry and Mining a year to prepare final plans for the installation of a concentration plant. Manganese ore produced in 1971 averaged 26.58% manganese. Total exports of rhodochrosite in 1971 were 103 short tons, valued at $172,000. The United States received 15 tons. Imports of manganese ore in 1971 totaled 25,000 tons.

Bolivia.—The small quantity of manganese ore produced (exported) in 1971 averaged 28% manganese.

Botswana.—Shipping reports submitted to the Botswana Geological Survey for 1971 showed that the manganese ore from the Lobatse South mine of Marble Lime & Associated Industries Ltd. averaged approximately 46% manganese dioxide, whereas that from the Kanye mine of Anglo American Corp. of South Africa Ltd. ranged from 45% to 68% manganese dioxide. Production for that year from the Kanye mine was about three times that from Lobatse South. The latter is located on the Transvaal border and is an extension of an operation on the Transvaal side of the border. It apparently operates sporadically on a small scale. The Kanye mine closed early in 1972; high transportation costs from mine to railhead at Lobatse were a factor in the closing. The manganese-producing areas of Botswana are heavily faulted and production has varied widely in grade.

Brazil.—The new pellet plant of Indústria e Comércio de Minérios S.A. (ICOMI) at the Amazon River port of Santana, Amapá Territory, produced its first pellets in May, but actual commercial operation was delayed by the problems normally attendant upon breaking-in a new plant. Design capacity is 235,000 short tons per year of pellets containing approximately 60% manganese. The complementary concentrator being built at the mine at Serra do Navio, designed to handle 200 short tons of ore per hour, underwent its first trial tests in December 1971.

Mine-run manganese ore produced in 1972 at Serra do Navio (ICOMI) totaled

1,968,000 short tons. Washed ore production was 1,514,000 tons averaging approximately 48% manganese plus 91,000 tons of washed fines averaging 35% manganese and sent to the new concentrator. Urucum production was 18,000 tons averaging 46.26% manganese, and the output of the Meridional mine in Minas Gerais was 97,000 tons averaging 37.91% manganese.

Manganese ore exports from Brazil in 1971 totaled 1,980,000 short tons, distributed as follows: United States, 771,000; Norway, 319,000; Canada, 146,000; West Germany, 128,000; Netherlands, 113,000; France, 109,000; Japan, 93,000; United Kingdom, 81,000; Italy, 79,000; Argentina, 45,000; Hungary, 24,000; Spain, 23,000; Yugoslavia, 23,000; Czechoslovakia, 21,000; and Mexico, 5,000.

Chile.—Manganese ore produced in both 1972 and 1971 averaged 41.6% managanese.

France.—Near the end of 1972, Ste. des Aciéries de Paris et d'Outreau, a producer of ferromanganese in which U.S. Steel Corp. has a 27% interest, completed construction of an additional blast furnace. This will result in increased ferromanganese production after completion of supporting facilities in early 1973.

Gabon.—Expansion completed in late 1972 brought annual production capacity to 2.3 million short tons of manganese ore. Shipments in 1972 were 2.0 million short tons. In addition to the metallurgical ore produced in the year, having a manganese content of 50% to 52%, there were 38,000 short tons of battery- and chemical-grade ore produced containing 83% to 85% manganese dioxide.

Ghana.—The Government announced its intention to reorganize all the country's operating mining companies; the Government would obtain 55% equity in each. African Manganese Co., a wholly owned subsidiary of Union Carbide Corp., is the only operating manganese mine in Ghana.

Greece.—Exports of pyrolusite concentrates in 1971, apparently battery-grade, totaled 5,200 short tons, of which 2,900 tons went to West Germany and 1,500 tons went to France, leaving the small remainder for other countries. Concentrates produced had a manganese content of 49% to 50%.

India.—Ferromanganese continued to be produced in the same seven plants. Production in 1972 was 179,000 short tons with installed annual capacity of 215,000 tons. Domestic consumption was approximately 89,000 tons, and exports totaled 62,000 tons. Distribution of the exports was similar to that of 1971, with the United States taking 33,000 tons; Sweden, 16,000 tons; Romania, 6,800 tons; Egypt, 5,200 tons; New Zealand, 900 tons; and Iran, 20 tons. Japan's omission in 1972 was the only significant change.

Of the 1,790,000 short tons of manganese ore reported as production for 1972, 1,032,000 tons or 57.6% was ferruginous manganese ore containing less than 35% manganese, 724,000 tons or 40.5% was classified as Second Grade manganese ore containing 35% to 48% manganese, 30,000 tons or 1.7% was First Grade manganese ore containing more than 48% manganese, and 3,600 tons or 0.2% was peroxide manganese ore having a maximum manganese dioxide content of 86%. Exports totaled 895,000 tons divided as follows: Ferruginous, 596,000 tons (Japan, 580,000; Czechoslovakia, 16,000); First Grade, 26,000 tons (United States, 17,000; Belgium, 9,000); Second Grade, 270,000 tons (Japan, 131,000; Czechoslovakia, 51,000; Bulgaria, 32,000; Belgium, 26,000; France, 15,000; Taiwan, 8,200; South Korea, 6,600); Peroxide, 2,525 tons (Japan, 2,500; United Kingdom, 25). Domestic consumption of manganese ore totaled 870,000 tons, of which 424,000 tons was for ferromanganese production, 435,000 tons for iron and steel, and 10,000 tons for dry cell manufacture, leaving 1,000 tons for other uses. Imports of manganese ore and concentrate totaled 5,800 tons, all of which was battery grade. Ghana supplied 4,100 tons; the United Kingdom, 1,500 tons; the Netherlands, 180 tons; and Greece, 5 tons.

Of a total of 370 registered manganese mines, 20 are in the public sector. From 310 to 315 of the registered mines may be expected to be active in an average year. Many of the private sector mines are small open pit operations producing less than 1,000 tons per year. Only Manganese Ore (India) Limited, a public sector company, can negotiate its own export contracts. Others must sell directly to the Government sales agency, Minerals and Metals Trading Corp. (MMTC), for rupees. The corporation then exports the ore under terms of trade agreements.

Indonesia.—For the last several years, all manganese ore produced has been of chemical grade, marketed in Japan and the Netherlands. Ore produced in 1972 had a reported manganese dioxide content of 90%. Production is by the Regional Government Enterprise in West Java.

Italy.—Reported average grade of manganese ore produced in 1972 was 25% manganese, the same as that for 1971. The sharp drop in production of manganese ore in 1971 was largely the result of reduced output of the Gambatesa (Genova) mine of Soc. Italsider at Varese Ligure in Genoa Province. Italy apparently has only one other manganese mine, the Cano Becco mine of Soc. Guiseppe Ucchedda at Carloforte in Cagliari Province. Its average annual production in the 1964–66 period was 100 tons of pyrolusite ore, averaging 30% manganese in 1966. Italy imported 320,000 short tons of manganese ore in 1971. The Republic of South Africa supplied 136,000 tons; Brazil, 78,000 tons; India, 38,000 tons; and Gabon, 20,000 tons.

Japan.—Capacity to produce electrolytic manganese metal was reported to be 17,200 short tons per year; Tekkosha Co. accounted for 13,200 tons, and Chuo Denko (Central Electric) accounted for 4,000 tons. Domestic demand was forecast at approximately 6,000 to 7,000 tons per year.[2] Tekkosha was planning a new plant to produce 500 to 1,000 tons per year. Because at least half of the output would be for export, serious consideration was being given to a foreign site.[3]

Hanshin Yosetsu Co. suspended production of synthetic manganese dioxide at the end of July, thereby dropping Japan's annual supply capacity to 43,600 short tons from 48,300 tons. Demand for domestic consumption and export was expected to be 44,000 to 45,000 tons in 1973. In anticipation of a supply shortage after 1974, Mitsui Mining and Smelting Co., Tekkosha Co., and other producers planned to start installing additional equipment and otherwise expand their plants in the first half of 1973.[4] Domestic demand in 1971 was 14,000 tons.[5]

Japan's production of dioxide ore or concentrate in 1972 was 850 short tons averaging 72.1% manganese dioxide; in 1971, it was 1,300 tons averaging 62.6% manganese dioxide. The grade of the metallurgical concentrate produced averaged 27.9% manganese in both years. Production of ferromanganese was 610,000 short tons in 1972 and 588,000 tons in 1971; silicomanganese, 378,000 tons in 1972 and 358,000 tons in 1971; electrolytic manganese metal, 8,456 tons in 1972 and 10,875 in 1971; and synthetic manganese dioxide, 43,440 in 1972 and 46,510 in 1971.

Malaysia.—There was 31,000 short tons of ferruginous manganese ore produced in 1972, compared with 29,000 tons in 1971.

Morocco.—All manganese ore produced in 1972 was chemical-grade concentrate averaging 84% manganese dioxide.

New Hebrides.—Manganese ore exports, reported as production in 1971, were all concentrates averaging 44.4% manganese.

Peru.—Production of manganese ore in 1972 averaged 27.8% manganese, compared with 29.9% in 1971.

Portugal.—The manganese ore produced in 1972 averaged 37% manganese; in 1971, it averaged 38%. In addition, approximately 50,000 short tons of manganiferous iron ore was produced each year; analyzing 42.4% iron and 7.8% manganese in 1972, and 42.6% iron and 7.7% manganese in 1971.

South Africa, Republic of.—Production of the various grades of metallurgical ore in 1972 was as follows, in short tons: 30 to 40% manganese, 2,362,000; 40% to 45%, 192,000; 45% to 48%, 128,000; and over 48%, 820,000. Local sales were, respectively, 452,000, 152,000, 56,000, and 187,000 tons. Of the chemical ore produced 95,000 tons contained 35% to 65% manganese dioxide, and 8,800 tons contained 65% to 75% manganese dioxide. Local sales were 90,000 and 5,800 tons, respectively. Production of ferruginous manganese ore, containing 15% to 30% manganese and 20% to 35% iron, totaled 112,000 tons. Exports were 215,000 tons and there were no local sales. Total exports of metallurgical ore were 2,486,000 tons.

By increasing cell and ancillary capacity, Electrolytic Metal Corp. (Pty) Ltd. (EMCOR), subsidiary of General Mining and Finance Corp. Ltd., planned a further increase in production of electrolytic manganese metal to 19,300 short tons, to be achieved as early as July 1973. All of EMCOR's production is marketed by A. Johnson and Co., Stockholm, Sweden, one of EMCOR's shareholders. Delta Metal Co. Ltd., a United Kingdom producer of copper alloy mill products, formed Delta Manganese (Pty) Ltd. to build and operate an electrolytic manganese metal plant at Nelspruit, eastern Transvaal. Production was scheduled to begin by the end of 1973 with an initial rated annual capacity of 17,600 short tons. The ultimate capacity of close to 31,000 tons was expected to be reached within about 4 years after the commencement of operations. Metallurgical ore is to be the raw material, and virtually all of the product will be exported.

[5] Metal Bulletin (London). No. 5698, May 9, 1972, p. 18.

Spain.—The manganese ore produced in 1972 had an average manganese content of 31.0%.

Surinam.—Several manganese deposits of possible economic interest were discovered in the period from 1955 to 1966. Of these the Lada Soela deposits on the Upper Tapanahony River are probably the most important. The laterite cap and surrounding float in the most promising part of these deposits was estimated to constitute a reserve of approximately 550,000 short tons averaging 40% manganese and 8% iron. This float is associated with 1.4 million tons of nodular laterite containing 15% manganese and 20% iron. Float and nodular laterite at Maripa Hill, Suriname River, was estimated at more than 1 million tons averaging 25% to 30% manganese. Reserves of Apoema Soela, Marowijne River, were estimated at 300,000 to 500,000 tons of ore averaging 30% manganese, and those of Plet Ridge, Upper Saramacca River, 100,000 to 150,000 tons containing about 35% manganese. Gondites (manganese quartzites) and lateritic manganese occurrences are widespread.[6]

Thailand.—Battery-grade ore (75% manganese dioxide) production in 1972 was 6,000 short tons; chemical-grade ore (minimum 75% manganese dioxide) production amounted to 26 tons. Exports of battery-grade were 1,100 tons in 1972 and 150 tons in 1971. Metallurgical ore exported in 1972 was 2,500 tons, compared with 9,000 tons in 1971.

United Kingdom.—All of the United Kingdom output of ferromanganese is by the Cleveland No. 5 blast furnace at the South Teesside Works of British Steel Corp. and the Cleveland No. 4 furnace. The total amounts to 4,000 to 5,000 tons per week.[7]

Zaire.—Société Minière de Kisenge (SMK) continued to mine ore containing 40% to 42% manganese from two open pits at Kisenge near the Angola border. Crushing, blending, and washing upgraded the ore to a shipping product containing 50% manganese for railing to the Angolan port of Lobito. Production in 1972 consisted of 313,000 short tons of ore containing 50% manganese, and 87,000 tons of fines that develop in the process and contain 46% to 48% manganese. These are also exported. Exports in 1972 included 7,700 tons of battery or chemical grade containing 80% manganese dioxide.

TECHNOLOGY

In an evaluation of the sulfatization-reduction process, a variation of the high-temperature differential sulfatization process developed at its Twin Cities Metallurgy Research Center for the recovery of manganese from low-grade Cuyuna Range (Minnesota) manganiferous iron ore, the Bureau of Mines estimated an operating cost of $211 per short ton of contained manganese to produce pellets containing approximately 90% Mn_3O_4. This was based upon a manganiferous iron ore feed containing 4.8% manganese and 33.4% iron for a plant with a productive capacity of 100 tons of contained manganese per day. The operating cost for a plant capable of producing 1,000 tons of contained manganese per day was estimated to be $158. These costs have the benefit of a credit for byproduct iron ore pellets. In the case of the 100-ton plant, this amounts to $120.50. In the process the ore is reacted with sulfur dioxide in shaft furnaces at temperatures between 1,100° and 1,560° F. In this temperature range the manganese is sulfatized but the iron is not. The resulting mixture of manganese sulfate and iron oxide is cooled and fed to a reduction furnace where the iron oxide is reduced to magnetite by the use of a reformed natural gas. The manganese is then leached out with water, and manganese sulfate crystals are recovered from the solution by evaporation. After pelletizing, these crystals are calcined to the final Mn_3O_4 product. Magnetic separation recovers the magnetite from the leach residue. This is pelletized and calcined to obtain the iron byproduct.[8]

[7] Iron and Steel (London). V. 45, No. 5, October 1972, p. 469.

A single-stage cocurrent leaching and thickening system[9] for extracting manganese from umber using simulated steel-mill sulfuric acid "pickle liquors" was found to be versatile and technically feasible, and to be simpler to operate and control than a three-stage countercurrent system reported earlier.[10] The work was at small pilot plant scale using umber from Cartersville, Ga., which analyzed 4.4% manganese and 42.0% iron. The use of a centrifuge in place of thickeners offered an advantage with respect to space, and compared favorably otherwise except that costs would be higher.

The geologic environments, and modes of origin, of three fairly common manganese oxide minerals—manganite, hausmannite, and braunite—were studied after positive identification by X-ray and spectrographic analysis of pure specimens. Before development of these analytical methods, identity was dependent on the procurement of good crystals or good chemical analysis of unadulterated specimens. As a result, many old reports of occurrences are suspect. From the present study, it was concluded that manganite is not as widespread as had been supposed, and that it is for the most part of hypogene origin; that is, deposited by warm or hot waters rising from depth. In many places, however, small quantities of manganite have been formed by surficial alteration of minerals such as rhodochrosite, rhodonite, or the sulfide, alabandite. Hausmannite was concluded to be most often, if not always, of hypogene origin, formed either in epigenetic veins or by hydrothermal alteration of manganese carbonate or oxide minerals. Braunite was, like manganite, either of hypogene origin deposited from solutions rising from depth or of supergene origin from descending surface waters. It was noted to be the dominant oxide in deposits that had undergone intense metamorphism, as in the case of certain Indian deposits.[11]

With the objective of utilizing New Brunswick's manganiferous shale, occurring near Woodstock and containing approximately 10% manganese, and the province's refractory base metal sulfide ores containing much massive pyrite, a process has been developed by W. J. Wark, Woodstock, N.B., that would result in recovery of manganese, copper, and lead metals, and a chemical-grade zinc sulfide. The shale is ground to 200 mesh and blended with the sulfide tailings, or comparably ground sulfide ore, in proper proportion for heating at low temperature to achieve an exchange of sulfur between the pyrite and the manganese. Manganese, copper, lead, and zinc sulfates are formed, with iron discarded as insoluble ferric oxide. Manganese metal produced electrolytically, besides being one of the final products, is used to reduce the copper and lead, and elemental sulfur is discharged.[12]

Researchers at the Bell Laboratories, Murray Hill, N.J., found that crushed single crystals of rare-earth oxides of manganese, and also those of cobalt, compared favorably with commercial platinum catalysts in oxidizing carbon monoxide for its control in automobile exhausts.[13] The work suggested that these lead-bearing manganites might have certain advantages, including that of cost and the fact that they are not poisoned by lead. However, more work is deemed necessary before commercial possibilities can be evaluated.[14] At about the same time, Japan's Mitsui Mining and Smelting Co. was reported to be almost ready to market its newly developed manganese catalytic afterburner in Japan at a rate of 5,000 units per month, and at a lower price than that for the platinum converter. It was reported that it would reduce nitrogen oxide and hydrocarbon emissions to some extent, as well as those of carbon monoxide.[15]

A discussion of the present status of undersea mining and exploration reported the continuing interest in the metalliferous muds of the Red Sea and the manganese nodules of the deep ocean floors. Process development work at the University of California at Berkeley has indicated that nickel, copper, and cobalt might be differentially leached from sea-floor manganese nodules at favorable costs. After crushing to approximately minus 20 mesh, most of the copper is leached with sulfuric acid at pH 2 and a temperature of approximately 25° C, followed by leaching most of the nickel from the remaining material at the same pH and a temperature of 50° C. It was reported that very little manganese or iron are dissolved.[16]

Mercury

By V. Anthony Cammarota, Jr.[1]

Primary mercury production of 7,286 flasks[2] in 1972, valued at $1.6 million, was the lowest since 1951. Only 21 mines were active during the year, compared with 56 mines in 1971, when 17,883 flasks were produced. By yearend a few mines remained, most of which were intermittent producers.

Secondary production of 12,651 flasks was down from the 1971 level. Some of the mercury came from a closed mercury-cell chlor-alkali plant and releases by the General Services Administration (GSA).

The consumption of 52,907 flasks in 1972 was slightly higher than in 1971. Increases were registered for agriculture, dental preparations, and industrial and control instruments, but the use in electrical apparatus declined.

Consumers worked off inventory as prices continued their decline to a low of $145 per flask in April. At the same time producers stockpiled metal. As prices recovered in the second half to finish the year at $285 per flask, producers took advantage of the rally to sell metal and consumers increased stocks.

Exports were down sharply. Imports were up slightly from 1971, with Algeria becoming a significant supplier. World production of mercury in 1972 decreased 6% from that of 1971. Spain increased production, whereas Canada, Italy, Mexico, and Yugoslavia showed declines.

The West German Government and a team of British and Australian divers both claimed ownership of an undisclosed quantity of mercury recovered from a U-boat sunk off the Malaysian coast during World War II. German U-boats are believed to have used mercury as ballast.

Legislation and Government Programs.——Government financial assistance on a participatory basis was available for mercury exploration projects through the Office of Minerals Exploration, U.S. Geological Survey, to the extent of 75% of the acceptable costs. No contracts were executed during 1972.

In July, GSA resumed its sale of surplus mercury on a sealed bid basis at the rate of 500 flasks per month. In August 450 flasks were sold at an average price of $225.77 per flask, but in September 49 flasks were sold for an average of $269.44 per flask. Total releases for the year of 512 flasks included 13 flasks transferred to the National Aeronautics and Space Administration.

As of December 31, 1972, total strategic stockpile accumulations from all programs stood at 200,105 flasks.

In March, the Environmental Protection Agency (EPA), under terms of the Federal Insecticide, Fungicide and Rodenticide Act, canceled all biocidal uses of mercury, and in addition suspended the registrations for alkyl compounds and nonalkyl uses on rice seed, in laundry products, and in marine antifouling paint.[3] The suspension order immediately halted all interstate shipment of the products. Under a cancellation order, sale and interstate commerce are permitted while an appeal is filed by manufacturers and a final decision is reached by a special scientific panel.

Pursuant to the Federal Food, Drug, and Cosmetic Act, the Food and Drug Administration proposed removing mercury from cosmetics other than those used around the eye.[4]

The goal of the Federal Water Pollution Control Act of 1972, as amended, is to

NA Not available.

[1] Excludes Government releases.

[2] Primary mercury only, including United States.

[3] Apparent consumption 1925–26, 1931, 1932, 1936–39; estimated by Bureau of Mines 1927–30; 1933–35; actual consumption 1940–72.

[4] Not separately classified.

eliminate all pollutant discharges by 1985. Title 3, Section 301, states that by July 1977 effluent limitations will be developed requiring best practicable control currently available, and by July 1983 best available technology economically achievable will be required. Chlor-alkali plants using the mercury cell would be affected by this law.

DOMESTIC PRODUCTION

The largest producer, New Idria Mining and Chemical Co., closed its New Idria mine in San Benito County, Calif., in May, but retained the mine on a standby basis for the balance of the year. Other large producing mines that closed during the year included the Corona, Gibraltar, and Mt. Jackson in California, and the Idaho-Almaden in Idaho. A total of 21 mines reported production, down from 56 in 1971. By yearend less than six remained active. In the first quarter production was about 3,200 flasks, but as mines closed or curtailed production, it fell to about 600 flasks in the fourth quarter.

Low prices and slackened demand were cited as reasons for the closures. Some exploration and development work was conducted by several small operators. The number of mines reporting outputs of 1,000 flasks or more decreased from six in 1971 to one in 1972. Properties producing 500 to 999 flasks decreased from six to four, and properties producing 100 to 499 flasks decreased from nine to seven. Of the total production of 7,286 flasks, 69% came from producers of 500 flasks or more and 26% from producers of 100 to 499 flasks. The remaining 5% came from other producers. Principal mines in 1972 were as follows:

State	County	Mine
PROPERTIES PRODUCING 1,000 FLASKS OR MORE		
California	Napa	Knoxville.
PROPERTIES PRODUCING 500 TO 999 FLASKS		
California	San Luis Obispo	Buena Vista.
Do	Sonoma	Culver-Baer.
Do	San Benito	New Idria.
Nevada	Pershing	Red Bird.
PROPERTIES PRODUCING 100 TO 499 FLASKS		
Alaska	Kuskokwim River Region	White Mountain.
California	Marin	Chileno Valley.
Do	Santa Clara	Guadalupe.
Do	Napa	Manhattan-One Shot.
Do	Sonoma	Mt. Jackson.
Do	Santa Clara	New Almaden.
Idaho	Washington	Idaho-Almaden.

Although there were 25 fewer mines in California in 1972 than in 1971, the State increased its share of total mercury production from 75% to 79%. A significant amount of mercury metal was produced at the Buena Vista mine from ore that was stockpiled during the past several years. The Knoxville mine, which had been closed for several years, produced a substantial quantity of metal from stockpiled ore and ore mined in 1972. The Santa Clara Quicksilver Co., which operated the New Almaden mine under lease from New Idria Mining, treated ore from underground workings and old mine dumps.

Nevada, with only three mines operating compared with eight in 1971, produced 11% of the total mercury. Near Lovelock, Pershing County, the Golden Cycle Technology Corp. produced cinnabar concentrate from the Pershing mine for export to the Republic of Korea and Taiwan, and also recovered a small amount of metallic mercury. The Carlin Gold Mining Co., which recovered mercury as a byproduct from its gold mine in Eureka County, was the only continuous producer of mercury in Nevada.

The Idaho-Almaden mine in Idaho, which accounted for 2% of the total U.S. production, closed in February. The White Mountain mine in Alaska shipped most of its cinnabar concentrate to Oregon for retorting, but exported a small quantity to

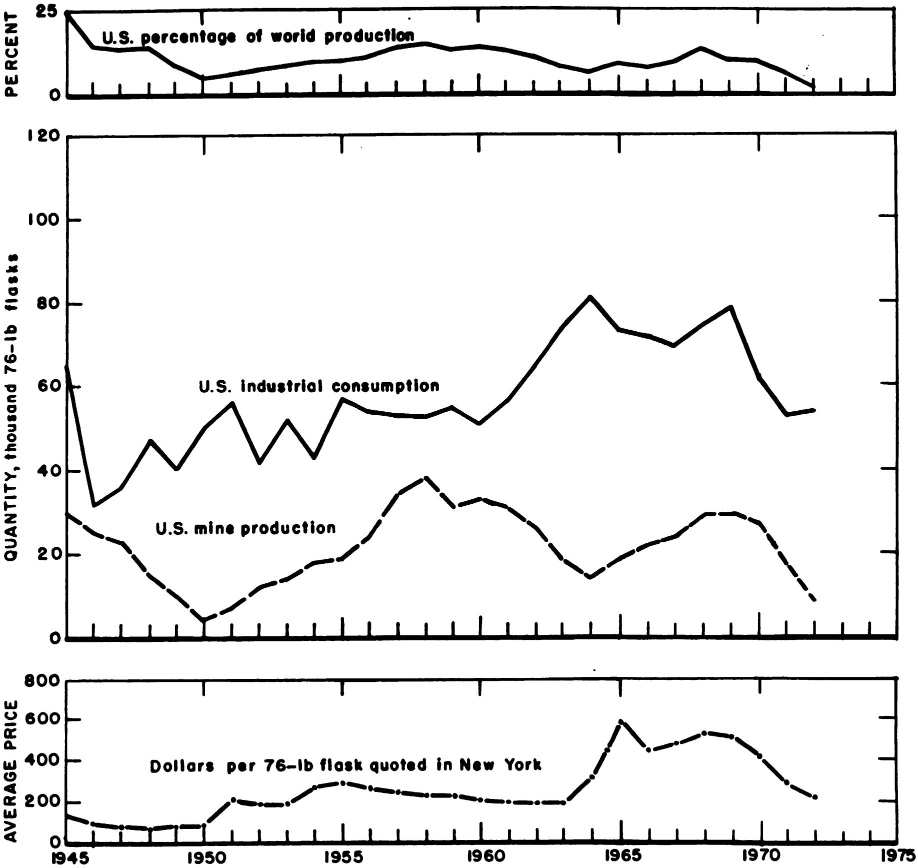

Figure 1.—Trends in production, consumption, and price of mercury.

the Orient. Two mines in Texas, the Fresno and Whit-Roy, were active for several months.

The St. Joe Minerals Corp. continued to recover byproduct mercury from its zinc smelter at Monaca, Pa. The zinc concentrate originated from the company's zinc mine in New York.

The average grade of all ore processed in 1972, including ore treated in concentrators, increased to 6.5 pounds of mercury per ton, the highest since 1964. About one-quarter of the ore treated contained over 20 pounds of mercury per ton.

The much-reduced level of GSA releases lowered secondary production of mercury to 12,651 flasks from 16,666 flasks in 1971 Dental amalgams, scrap batteries, various types of sludges, two dismantled mercury-cell chlor-alkali plants, and discarded mercury-containing instruments were the major sources of secondary mercury.

Table 4.—Mercury ore treated and mercury produced in the United States [1]

Year	Ore treated (short tons)	Mercury produced	
		Flasks	Pounds per ton of ore
1968	434,193	28,857	5.1

Year	Flasks [1]
1968	34,380
1969	13,650
1970	8,051
1971	16,666
1972	12,651

[1] Includes GSA releases.

CONSUMPTION AND USES

Consumption at 52,907 flasks was 1% higher than in 1971. Increased consumption was noted for agriculture, dental preparations, and industrial and control instruments. Electrical apparatus, down 8%, showed the largest decline of the major uses, mainly because of a fall in consumption for batteries. Mercury usage for the electrolytic preparation of chlorine and caustic soda fell for the third consecutive year. Secondary mercury was transferred from a dismantled chlor-alkali facility to other plants within the Olin Corp. to increase the capacity of existing cells. The major uses of mercury were electrical apparatus, 29%; electrolytic preparation of chlorine and caustic soda, 22%; antifouling and mildew-proofing for paint, 16%; and industrial and control instruments, 12%.

Although total chlorine production increased by 6% to 9.9 million short tons, only 24.2% of the total was produced in mercury cells. In 1971, 27.2% of the chlorine was produced in mercury cells, with

r Revised.

the high of 28.6% being achieved in 1968. Consumption of mercury per ton of chlorine produced, 0.37 pound, remained at the 1971 level. Planned expansions are expected to increase chlorine capacity about 15% to 20% by the end of 1974, but none of the new capacity will use mercury cells. Sobin Chlor Alkali Inc. installed the borohydride process for recovering mercury from water effluent and a molecular sieve system for mercury vapor recovery from the hydrogen gas stream. The recovered mercury is being reused at the plant. Olin Corp. closed its Saltville, Va., mercury-cell facility and will use the mercury to fill the demand at its other plants.

Manufacturers of mercury compounds used in paint filed an appeal of EPA's order canceling the registration of these materials for use in mildew-proofing paint. Consumption of mercury in mildew-proofing paint remained generally unchanged from 1971. Apparently some substitution of mercury compounds by organics took place during the year, as indicated by the fact that the total volume of paint shipments was up 6% over last year according to the Bureau of the Census.

PRICES

The price of mercury continued its decline into 1972, reaching $145 per flask in late April, the lowest level in 22 years. Sluggish demand and the intention of EPA to ban the use of mercury in paint were the major reasons for the decline. From May through September the price recovered dramatically to the $265 to $275 range. The market was buoyed by the news of a significant cutback in Canadian production, a bone-dry supply, and the conservative selling policy of GSA for its surplus mercury in July and August. In addition, there were reports that an effort was underway by the major world producers to hold back offerings to improve prices. Prices dropped somewhat in the fall but recovered to finish the year at $280 to $285. The average price of mercury at New York was $218.28 per flask in 1972.

Prices on the London market were below New York prices by about $5 to $23 per flask. In midyear optimism generated by purchase tenders from India, Poland, and Colombia lifted prices. The European market was weak from a heavy influx late in the year of the U.S.S.R. mercury which fetched lower prices. Also, some traders believed the low prices were the result of manipulative moves on the part of trading interests with buying contracts.

[1] Metals Week, New York.

[2] Metal Bulletin prices. In 1971, reported in terms of pounds sterling converted to U.S. dollars by using average rates of exchange recorded by Federal Reserve Board. In 1972, reported in terms of U.S. dollars.

FOREIGN TRADE

Mercury exports decreased significantly to 400 flasks from 7,232 flasks in 1971. The major recipient was East Germany with 250 flasks, followed by Canada, 57 flasks, Colombia, 18 flasks, and Venezuela, 17 flasks. Of the 563 flasks reexported, East Germany received 550 flasks and Sweden 13 flasks.

Imports for consumption, which include mercury imported for immediate consumption plus material withdrawn from bonded warehouses, increased by 1% to 28,834 flasks. General imports, which include mercury imported for immediate consumption

[1] General imports in 1970 were 21,672 flasks ($8,962,335); Spain supplied 1,702 flasks ($805,504). In 1971, 29,750 flasks ($8,500,607) were imported; Spain supplied 3,353 flasks ($970,028) and Mexico, 4,886 flasks ($1,184,826). In 1972 imports comprised 29,179 flasks ($6,232,570); Peru supplied 2,210 flasks ($458,495), Yugoslavia 1,402 flasks ($298,345), and Spain 1,120 flasks ($254,677).

[2] Less than ½ unit.

[3] Reclaimed metal.

plus material entering the country under bond, were 29,179 flasks. The major suppliers were Canada, 48%; Mexico, 19%; Algeria, 10%; and Spain, 6%. Smaller amounts of prime virgin metal came from Peru, Turkey, and Yugoslavia. Ore containing about 2 flasks of metal was imported from Peru. Trade in mercury compounds, including cinnabar concentrate, was small. Included in the import figures are 1,329 flasks entering the country as secondary metal from Norway and 2 flasks contained in scrap from Mexico.

The U.S. rate of duty on mercury imports during the year was $9.50 per flask.

WORLD REVIEW

World mercury production decreased to 279,508 flasks from 298,552 flasks in 1971. Spain, the U.S.S.R., and Italy were the three largest producers, accounting for 55% of the total. Canada, Italy, and Spain curtailed production during the year in the face of soft prices, slackening demand, and in the case of the latter two, excessive metal inventory. Europe was rife with rumors that representatives of the industry from Algeria, Italy, Mexico, Spain, and Yugoslavia had met in France in December to discuss a base price for mercury.

Algeria negotiated contracts for the sale of its mercury production to firms in the United States, Europe, and Japan. The People's Republic of China, which in the past exported considerable volume of metal to the U.S.S.R., reportedly cut exports to meet higher home consumption and stockpiling objectives. Mercury mining in Turkey was reviewed from its beginning 8,000 years ago to the present.[5] Developments in other countries were as follows:

Table 12.—Mercury: World production, by country

[e] Estimate. [p] Preliminary. [r] Revised.
[1] Production target set for 1972.
[2] Output of Cominco Ltd.; excludes production (if any) by minor producers.

Canada.—Cominco Ltd., reduced its mercury production in midyear with the result that total production was 21% less than in 1971. Ore production from the Pinchi Lake mine amounted to 203,000 tons, compared with 248,000 tons in 1971. Assuming that all the ore mined was treated to produce metal, the ore grade declined from 5.7 pounds of mercury per ton in 1971 to 5.5 pounds in 1972. Ore reserves were reported by Cominco to be 1,800,000 tons containing 133,000 flasks of mercury.

Italy.—Monte Amiata Società Mineraria per Azioni, Italy's leading producer, reportedly cut its output of mercury during the year, but total Italian production was down only slightly from 1971 levels.

The company completed the deepening of the San Callisto pit at Abbadia San Salvatore and began working on the Garibaldi pit. In addition, Monte Amiata dug 2,800 feet of new tunnels and carried out about 330 feet of exploratory soundings.

Stabilimento Minerario del Siele, the second largest producer, also announced production cutbacks. A major part of the plant at Santa Fiora in the Province of Grosseto was closed.

Exports were only 9,631 flasks for the first 11 months compared with 15,201 flasks for all of 1971. Press releases in Italy reported that since domestic consumption of mercury declined substantially, much of the mercury output was stockpiled.

Mexico.—Output declined significantly because of the financial problems of Mercurio Mexicana, S.A. de C.V., the largest producer. As prices fell the company could not meet the costs of expanding its flotation mill or the payroll for its workers who eventually took over the mine. The company closed its mine in midyear and declared bankruptcy. Fomento Minero, the Mexican Bureau of Mines, was negotiating to reopen the mine under government control. Many small mines closed in the summer but started up again late in the year. About twelve of the largest producers formed an organization to avoid internal competition and to act as a marketing agent for foreign sales.

Spain.—Production increased by 19% to an estimated 60,500 flasks, even though two small producers closed their operations in midyear. Astur Belga de Minas, S.A., and Minas de la Soterrana, S.A., suspended operations and dismissed 330 workers to prevent financial losses to the companies. By yearend plans were underway to resume operations.

Minas de Almadén, the State-owned company, had several projects underway, including the installation of a conveyor belt system and the utilization of propane gas and automatic controls in the furnaces of the metallurgical plant.

U.S.S.R.—Plans have been approved to build a large mercury mining and metallurgical complex near Magadan on the Chukota Peninsula. Commercial quantities of cinnabar were proved in the area, which has recently had an increasing production of mercury.

TECHNOLOGY

Because of the concern over the level of mercury in the environment, available data on mercury content in rocks, ores, minerals, soil, water, and plants were compiled with a view toward elucidating the role of natural processes in releasing mercury to the environment. The cycle of interconversions for mercury in nature shows that all of the oxidation states are readily interconvertible given the appropriate physical, chemical, and biological conditions.[6]

A process was developed by Bunker Hill Co. to remove mercury from the sulfuric acid produced from roasting zinc ores.[7] Details of the process have not been disclosed, to protect its patentability. In the Netherlands, quantities of mercury are being extracted from the Groningen natural gas field.[8] The company is installing equipment for the industrial recovery of more mercury found with solid contaminants, including sand and clay.

A method of determining traces of mercury in liquids, sensitive to about 1 part per billion, was developed.[9] After selectively adsorbing the mercury on gold foil, it is heated to release the mercury vapor in an inert gas mixture where it is detected by a fluorescence spectrometer.

Interest continued on the development of methods for the removal of mercury from industrial waste solutions. In one system, high-molecular-weight amines are used to extract mercury quantitatively from alkaline as well as acidic brine solutions.[10] Regeneration of the amine solvent is readily achieved by stripping the mercury with aqueous solutions of nitric acid or other amines, or reduction of the mercury to metal by aluminum. A process capable of reducing the mercury content of waste water to less than 5 parts per billion utilizes an ion exchange resin.[11] Passage through the resin reduces the mercury content of the water from about 20 parts per million (ppm) to 0.1 ppm. The resulting effluent is subsequently treated through a second patented resin to reduce further the mercury content. The ion exchange resin is regenerated and metallic mercury is recovered. Treatment of the brine-settler mud in chlorine plants involves leaching with hypochlorite solution to form a soluble mercury complex and passage of the solution through ion exchange resins to recover the mercury. Mercury in vapors emerging from chlor-alkali plants has been successfully removed by scrubbing with an alkaline sodium hypochlorite-sodium chloride solution[12] or by passing the gas through molecular sieves.[13]

At the Bureau of Mines Reno Metallurgy Research Center, Reno, Nev., mercury extractions of 98% were obtained in pilot plant studies using the patented electrooxidation process on cinnabar ore from the Cordero mine, McDermitt, Nev.[14] A sample of Peruvian ore containing 1.8 pounds of mercury per ton was treated with the achievement of 94% extraction efficiency. A chemically modified cellulose was developed which appears highly effective for removing mercuric ions from water over a wide pH range, and in the presence of other metal ions and complexing agents.

Several new uses for mercury were publicized during the year. A method was developed using molten mercuric bromide as a heavy liquid in the separation of high-density minerals, such as uraninite from zircon in artificial mixtures.[15] An electrochemical method for the preparation of mercury telluride, which is an excellent infrared detector material, was described.[16] Research is being conducted on the use of a mercury cathode in the electrolysis of aqueous solutions of copper to produce the powder.[17] The same technique should be possible with other metals that are insoluble in mercury, such as nickel and iron.

A survey of the mercury reprocessing industry was undertaken by the Oak Ridge National Laboratory to obtain a better understanding of the technology and economics of recycling.[18] It was found that about one-third of the secondary mercury came from instruments and electrical apparatus, about one-quarter each from research laboratories and industrial scrap, about one-tenth from batteries, and the remainder from miscellaneous sources.

Mica

By Benjamin Petkof [1]

Scrap and flake mica production reached the highest output ever recorded in the United States during 1972. Only a minor quantity of low-quality sheet mica was produced during the year in only one State. Ground mica production increased in both quantity and value. All exports of mica declined in quantity but increased in value. Imports of unprocessed and processed sheet increased, and scrap imports declined. The domestic consumption of all forms of sheet mica varied little from that of the previous year.

DOMESTIC PRODUCTION

Sheet Mica.—Slightly over 7 short tons of sheet mica, valued at $7,000, was produced in Colorado during 1972. The production consisted of low-value punch and circle mica. The outlook for any large future production of any quality of sheet mica remained small.

Scrap and Flake Mica.—The production of scrap and flake mica reached an alltime high of 159,536 short tons valued at $4,353,313. This was an increase of 26% in quantity and 49% in value. North Carolina was the major scrap and flake producing State with almost 57% of total production. The remaining output came from Alabama, Arizona, Connecticut, Georgia, New Mexico, Pennsylvania, South Dakota, and South Carolina. Flake mica was obtained primarily by the beneficiation of material from pegmatite and kaolin deposits. The domestic output of scrap and flake was processed to small particle size mica for various industrial end uses.

Ground Mica.—Sales of ground mica increased 7% in both quantity and value over those of 1971. Dry-ground mica accounted for 80% of total sales. Sixteen companies, operating a total of 20 plants, processed scrap and flake to a small particle size; of these plants, 14 produced dry-ground mica; 3, wet-ground; and 3, both wet- and dry-ground.

[2] Data may not add to total shown because of independent rounding.

CONSUMPTION AND USES

Sheet Mica.— The consumption of all forms of sheet mica, consisting of block, film, and splittings varied only slightly from that of the previous year. Splittings were the major form of sheet mica consumed.

About 1.1 million pounds of block mica was consumed for the fabrication of vacuum tubes, capacitors, and various other electrical and nonelectrical items. Of the total consumption, vacuum tubes required 70% and capacitors accounted for 1%. Lower than Stained quality was in greatest demand and accounted for 64% of total consumption; Stained, 35%; and Good Stained or better, the remainder. Only a small quantity of mica film was consumed primarily for the fabrication of capacitors.

Muscovite block and film was consumed by 14 companies in Seven States. New Jersey with four consuming plants, New York with three, North Carolina with two, and Pennsylvania with one, consumed 77% of the domestically fabricated block and film mica. The consumption of phlogopite block increased 11% to 74,199 pounds.

Total consumption of splittings increased almost 4% from that of 1971. India and the Malagasy Republic continued to supply the bulk of the splittings consumed domestically. Splittings were fabricated into various built-up mica products by 10 companies with 11 plants in seven States. Four companies, with five plants located in New Hampshire, New York, Ohio, and Pennsylvania, consumed almost 3.6 million pounds of splittings or 83% of total consumption.

Built-up Mica.—This mica-based alternate material was produced in various forms, primarily for use as an electrical insulating material. The production of built-up mica products in 1972 declined 5% in quantity and 10% in value from

[1] Includes mica used for molded electric insulation, annealing, well drilling, textile and decorative coating, texture paint, and uses indicated by symbol W.

[2] Data may not add to totals shown because of independent rounding.

that of the previous year. The forms of built-up mica in greatest demand was segment plate (30%), tape (25%), and molding plate (23%).

Reconstituted Mica.—Three companies continued to manufacture this mica-based alternate material from good-quality delaminated scrap mica. The manufacturing companies were the General Electric Co. at Schenectady, N.Y., the Samica Corp. at Rutland, Vt., and the Acim Paper Corp. at New Hyde Park, N.Y. There were no data available relating to the quantity and value of the reconstituted mica produced during the year.

STOCKS

At yearend there was about 2.5 million pounds of sheet mica in fabricators' stocks. Of this quantity, 73% was splittings, and the remainder was almost entirely of block. Only a minor quantity consisted of film. This information was obtained by direct canvass of fabricators of sheet mica. Similar information is not available for scrap and flake mica, but it is thought that producers maintain stock inventories equal to 5% or 10% of domestic production.

PRICES

The average value of the domestically produced uncut punch ad circle mica in 1972 was $0.50 per pound, an increase of $0.11 per pound over that of the previous year. The average value of muscovite sheet mica in 1972, based on consumption data, was as follows: block, $1.62 per pound; film $6.70 per pound; and splittings, $0.41 per pound. The average value of phlogopite sheet mica, also based on consumption data, was as follows: phlogopite block, $1.84 per pound and phlogopite splittings, $1.43 per pound.

The average value of scrap and flake mica produced during the year was $27.29 per ton. Prices for ground mica, prepared from scrap and flake, quoted in the Chemical Marketing Reporter were essentially unchanged from the previous year. Yearend prices are shown in table 9.

Table 9.—Price of dry-or wet-ground mica in the United States in 1972[1]

	Cents per pound
Dry-ground:	
Joint cement, 100 mesh	3¾–5
Plastic, 100 mesh	3¾–5
Roofing, 20 to 80 mesh	2–8
Wet-ground:[2]	
Paint or lacquer, 325 mesh	9
Rubber	9
Wall paper	10

[1] In bags at works, carlots, unless otherwise noted.

[2] Freight allowed east of the Mississippi River, ½ cent higher west of the Mississippi River, 1 cent higher west of the Rockies.

Source: Chemical Marketing Reporter. V. 203, No. 1, Jan. 1, 1973.

FOREIGN TRADE

All classes of mica exports declined 1% in quantity but increased 26% in value from that of the previous year. Almost 70% of the sheet, scrap and flake, and ground mica exported, was shipped to Canada, France, Japan, and Venezuela. Reported export data do not provide information on the grade or type of mica exported but it is assumed that the major portion of the material exported is ground mica.

Imports of scrap and waste mica declined 64% in both quantity and value. Imports of sheet mica increased slightly in quantity but declined slightly in value. Processed mica imports increased 26% in quantity and 29% in value.

[1] In addition to classes shown for 1970, of untrimmed phlogopite from which no piece over 2 by 1 inch may be cut was 33,069 pounds ($705) from Brazil; none in 1971 and 1972.

[2] Less than ½ unit.

WORLD REVIEW

World mica production remained strong during the year with major producing countries continuing to maintain their output. India and the Malagasy Republic remained the major producers of sheet muscovite and phlogopite respectively. The United States dominated the area of scrap and flake production.

India.—On January 25, 1972, the Indian Government announced that all mica exports were to be channelled through the Minerals and Metals Trading Corp. of India (MMTC). The MMTC was expected to purchase mica from small mine owners for export. The corporation does not control exports of manufactured, fabricated, built-up, reconstituted, or ground mica. In April 1972, MMTC agreed to consider requests from private mica exporters to negotiate sales directly. Exporters with current contracts or agreements with foreign buyers were permitted to function as previously, but on behalf of MMTC and at current minimum prices. An additional proviso stipulated that all letters of credit were to be made to the favor of MMTC.

During 1972, 422 privately owned mines reported production. About 100 of these mines claimed that their production was in excess of 50 short tons per year. The output of the remaining mines, which were essentially cottage industry-type operations, varied from 5 to 30 tons per year, each. Hand-mining methods were used in open pits throughout the industry where operations rarely exceeded depths of 50 feet.

[e] Estimate. [p] Preliminary. [r] Revised.

[1] In addition to the countries listed, the People's Republic of China, Romania, Southern Rhodesia, South-West Africa, Sweden and the U.S.S.R. are known to produce mica, but available information is inadequate to make reliable estimates of output levels.

[2] Exports.

[3] Includes micanite and other built-up.

[4] Includes condenser film, washer, and discs.

[5] Includes sheets, strips, and powder.

Crude mica production, based on exports plus consumption, increased slightly from 35,119 tons in 1971 to 37,299 tons in 1972. Exports also increased from 26,319 tons valued at $21.7 million in 1971 to 27,949 tons valued at $25.3 million in 1972. Thirty-two percent of exports in both 1971 and 1972 consisted of sheet mica. The remainder consisted of other forms of processed and scrap mica.

TECHNOLOGY

The work of the Bureau of Mines in the area of recovery of mica concentrates by flotation from weathered mica pegmatites and micaceous schist ores has been reviewed. The acid cationic and alkaline anionic-cationic method for the recovery of coarse and fine mica, respectively, are discussed and flowsheets for their use were provided. In addition, mining, recovery, and grinding of mica were discussed.[2]

Batch laboratory scale tests were run on several industrial minerals that included mica to determine the optimum grinding constants. The test used an attrition grinding process developed previously by the Bureau of Mines.[3]

A method has been developed to break apart natural, synthetic, or mixtures of mica by initially heating the material to drive off the water of hydration. The heated material is then broken apart in oriented streams of an inert gas such as argon to produce thin, smooth-surfaced particles, or flakes with a high specific surface area and a high ratio of length to thickness.[4]

Molybdenum

By Andrew Kuklis[1]

World molybdenum output rose 4.4 million pounds in 1972 and was 2% higher than in 1971. Molybdenum remained in oversupply because of an increase in new production capacity that resulted in a significant rise in stocks during 1972. To arrest the alarming growth of stocks, some mines shutdown, and others reduced molybdenum production. Yearend world molybdenum stocks were estimated to exceed the current annual consumption rate.

Based upon known geological occurrences, production trends of the past decade, and current projects under development, the supply of molybdenum was expected to be adequate to meet increasing demand during the remaining years of the 20th century.

Legislation and Government Programs.—The House Armed Services Committee approved a bill to dispose of molybdenum in the national stockpile. All the molybdenum in the stockpile was declared in excess of national emergency requirements because an adequate supply was available from domestic resources. However, because of other legislative matters, the House of Representatives did not take action on the bill. At yearend, molybdenum in the national stockpile totaled 46.8 million pounds, same as at yearend 1971. Approximately 5.5 million pounds of molybdenum was classed as sold but unshipped (table 3).

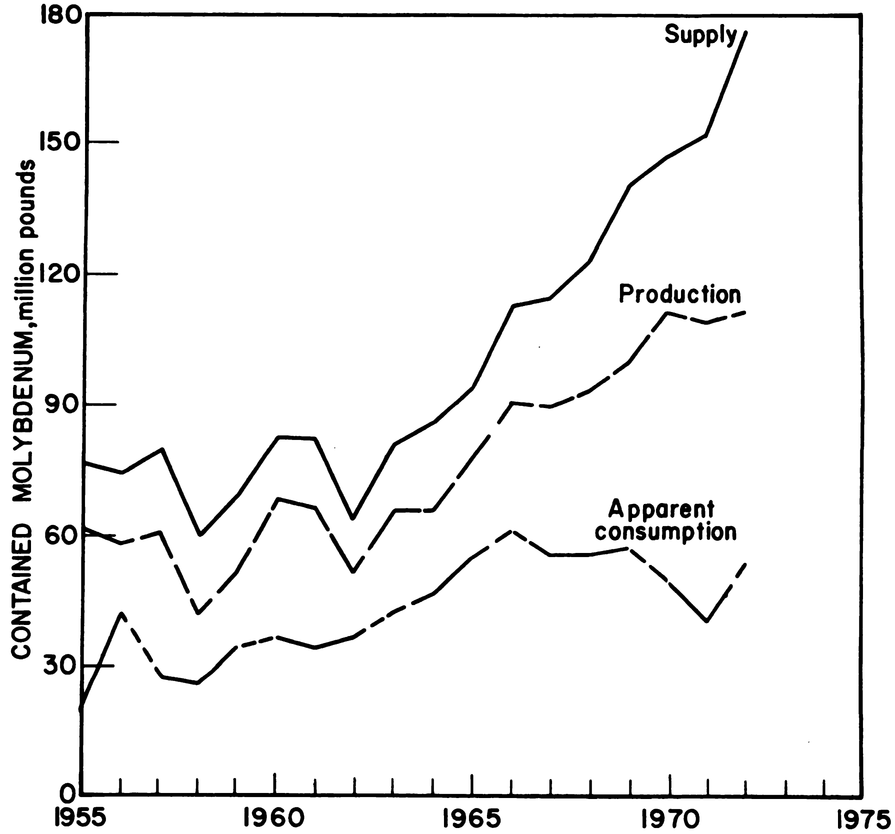

Figure 1.—Apparent consumption, production, and supply of molybdenum in the United States.

DOMESTIC PRODUCTION

Domestic output totaled 112.1 million pounds of molybdenum, 2% higher than in 1971. Production reached an alltime high exceeding by 786,000 pounds the previous record year in 1970. Molybdenum remained in oversupply because of declining exports in recent years and lower than anticipated domestic demand that resulted in a rise in stocks.

Molybdenum production from primary sources approximated that produced in 1971. Three operations mined over 21 million tons of ore containing from 4 to 7 pounds of molybdenum per ton. As in past years, the Climax mine in Colorado of American Metal Climax, Inc. (AMAX), was the world's largest producer.

Increased byproduct molybdenum production capacities at copper porphyry plants, especially those completed in 1971, resulted in an 8% higher output from these sources. Molybdenum production obtained from byproduct sources rose to 37% from the 35% reported in 1971, continuing the upward trend of past years. The significance of this trend is apparent when related to past molybdenum production data. For example, in 1967, molybdenum output from these sources accounted for only 26% of domestic production; hence, in 5 years the percent of molybdenum production from byproduct sources rose over 42%.

Byproduct molybdenum from copper porphyry ores was produced at 14 plants, one less than in 1971. The Esperanza facility of Duval Corp. was closed during the year. Seven plants reported increased output, and seven had lower production. Molybdenum recovery at uranium and tungsten operations increased by 6% and 2% respectively, compared with 1971. The byproduct plants reportedly processed over 70 million tons of ore containing from 0.3 to 1.2 pounds of molybdenum per ton.

Yearend molybdenum stocks at mines increased 5.3 million pounds at byproduct operations but decreased about 600,000 pounds at primary operations.

According to 1972 data, Pennzoil Co., parent company of Duval Corp. and Duval Sierrita Corp., was the leading domestic producer of byproduct molybdenum. Kennecott Copper Corp., with four operations, remained in second place. Other large producers of byproduct molybdenum were, in order of output, Magma Copper Co., The Anaconda Company, and American Smelting and Refining Co. (Asarco).

Pima Mining Co. completed expansion of mine and concentrator capacity near Tucson, Ariz. The capacity of the facility was increased from 40,000 tons to 54,000 tons per day. Ore reserves at yearend 1972 were reported at 240 million tons having an average grade of 0.5% copper and sufficient molybdenum to justify recovery.

Cities Service Co. was developing a low-grade copper-molybdenum deposit at a cost of about $100 million near Pinto Valley, 8 miles west of Miami, Ariz. Capacity of the open pit mining facility reportedly will exceed 40,000 tons of ore per day. Approximately 62,500 tons of copper and an undisclosed amount of molybdenum will be recovered from the ore. Mine and milling operations were expected to commence in mid-1974 and reach designed capacity in early 1975. Work projects underway during 1972 were construction of a mill and preproduction stripping.

Molybdenum Corp. of America (Molycorp) increased molybdenum recovery at its Questa operation over 9% compared with that of 1971. Increased output was due to higher molybdenum content of ore milled. Pit stripping operations were conducted in accordance with a restrictive mining plan adopted in mid-1971 to lower development costs. It was reported that uninterrupted mining operations after 1976 would necessitate an increase in pit development expenditures during 1974. Furthermore, an increase in such expenditures for continued development of the mine would be justified only if the present weak price trend of molybdenum was reversed.

AMAX was developing an open pit mine on its Climax molybdenum deposit to supplement current underground production at the Climax mine in Lake County, Colo. The $40 million investment will increase ore output to 60,000 tons per day, of which 43,000 tons would be from underground operations, and the remainder from the open pit. Approximately 185 million tons of low-grade ore (0.28% molybdenite) were added to reserves at the Climax deposit, ore which could not be economically mined by underground methods. Total ore reserves reportedly were estimated at 500 million tons having an average grade of 0.35% molybdenite. About 260 million tons of waste material will be removed to develop the open pit mine. The combined open pit and underground operation will increase the flexibility of the Climax mine in meeting fluctuations in molybdenum demand. AMAX operations were described.[2]

Mine development continued at AMAX's Henderson molybdenum mine near Empire, Colo. The No. 2 shaft, a 28-foot-diameter unit, was bottomed out at 3,100 feet on June 14 by Harrison Western Corp., an international mine development contractor. A main ore haulage level was constructed at the 7500 elevation level where ore will be loaded into railroad cars for transportation through the tunnel to the mill. Good progress was reportedly made in driving a 9.3-mile ore haulage tunnel. At yearend, construction was conducted from two directions, from the underground mine and from the surface on the western slope. The $250 million mine and mill facility ultimately will produce 50 million pounds of molybdenum annually.

Commercial-ore-grade material was encountered by underground tunneling and drilling at the Thompson Creek molybdenum deposit in central Idaho by Cyprus Mines Corp. The company reported that the deposit contains about 100 million tons of ore assaying 0.148% molybdenite. Additional feasibility studies were underway regarding the economics and time frame for developing the property.

---

[2] Engineering and Mining Journal. AMAX in Perspective. V. 173, No. 9, September 1972, pp. 93–103.

Phelps Dodge Corp. negotiated a joint exploration agreement with Catla Mine Inc. on a copper-molybdenum mineralization in northern Elko County, Ariz. Catla Mine Inc. owns 471 mineral claims in the area and conducted considerable exploratory drilling in past years. An estimated 8 million tons of ore averaging 2.3% copper equivalent was reportedly drilled out on the leases.

At yearend, the copper-molybdenum mine and mill of Duval Sierrita Corp., Tucson, Ariz., reached designed capacity. The mill reportedly processed an average of 84,000 tons of ore daily during November and December. It was expected that the production potential of the facility would be reached during 1973. The $165 million mining, milling, and roasting complex commenced operations at midyear 1970.

[1] Includes calcium molybdate.

[2] Includes purified molybdenum disulfide, molybdenite concentrate added directly to steel, molybdenum metal powder, molybdenum metal pellets, and other molybdenum materials.

[3] Includes magnetic and nonferrous alloys.

CONSUMPTION AND USES

Domestic consumption of molybdenum in concentrate declined nearly 6% compared with 1971 figures. Most of the concentrate, except that consumed in producing purified molybdenum disulfide, was converted to molybdic oxide for use as such or to produce other molybdenum products. Output of purified molybdenum disulfide for lubricants increased significantly compared with that of 1971.

Domestic end use consumption of molybdenum material rose 4.6 million pounds in 1972 and was about 11% higher than in 1971 (table 5). The increase was the first in 2 years, but remained about 12% below the record year of 1969. Higher consumption was due to increased production of alloy steel. Over 84% of molybdenum products were consumed by the iron and steel industry, the remainder for metal powder and in chemical uses. Steel manufacturers take advantage of unique properties such as hardenability, corrosion resistance, strengthening, and toughness that molybdenum conveys to various types of steel. In the metal powder and chemical markets, molybdenum products were consumed to produce specialty metal products, catalysts, and pigments. Molybdenum consumed in its various end uses was in the form of molybdic oxide (66%), ferromolybdenum (20%), ammonium and sodium molybdate (2%), and other materials (12%).

Development of new markets to increase consumption of molybdenum products was intensified, especially in alloy steel and for chemical applications.

The new high-strength steel containing molybdenum-columbium introduced in 1971 for manufacture of gas transmission pipe continued to gain acceptance in 1972. Two Canadian pipeline companies utilized approximately 200 miles of this line pipe for transporting natural gas to consumers and field tests for similar applications were being conducted in other countries.

A new 18% chromium, 2% molybdenum stainless steel was produced commercially by steel companies in the United States and abroad for use in hot water heaters, heat exchangers, and other applications where heat and corrosion problems exist. The molybdenum-type stainless steel has superior properties to nickel-type material for some applications, and in addition, it is lower in raw material costs.

A special grease-grade molydisulfide product was marketed in 1972. The product was reportedly easier to use than the present grade and permits grease manufacturers to reduce compounding costs.

A major paint and pigment company adopted a new "White Moly" product in manufacturing pigments. The material was developed by AMAX for nontoxic corrosion-inhibitive coating systems and designed for solvent-based paints in a wide range of colors. In addition to being nontoxic, White Moly was cost competitive with existing toxic materials on an equal cost basis.

STOCKS

The industrial molybdenum inventory, reported to the Bureau of Mines, was 79.0 million pounds, comprised of 45.2 million pounds at mines and plants, 28.9 million pounds at producer plants, and 4.9 million pounds at consumer plants. Molybdenum in stock at mines and plants rose nearly 56%, those at consumer plants rose over 22%, but those at producer plants declined 7% compared with 1971 figures.

PRICES

Published prices for high-quality molybdenum concentrate and primary products were unchanged from yearend 1971. However, because of an oversupply condition, some discounting was prevalent during 1972, particularly in the byproduct markets. A leading producer of byproduct molybdenum announced price reductions twice during the year on two grades of molybdic oxide. Byproduct concentrate sales were reportedly made at $1.45 to $1.60 per pound, and some Chilean material was sold at $1.40 per pound. Ferromolybdenum reportedly was discounted about 7 cents below the published price.

For the short range, future prices may not increase with inflation. On the other hand, reasonably stable prices are expected to favor increased consumption in industrial plants and equipment.

FOREIGN TRADE

U.S. exports of molybdenum in ore and concentrate, including roasted concentrate, declined for the fourth consecutive year (table 7). The Netherlands again was the principal recipient, receiving 42% of the total. Most of the material entering the Netherlands was reshipped to other European countries.

Despite a decline in exports, the United States continued to be a major supplier of molybdenum for the world. Foreign markets received 39% of the nation's output compared with 42% and 50% in 1971 and 1970, respectively. The U.S. share of the foreign market was expected to decline further because of the competition from excess production capacity in Canada and Chile.

Table 6.—Molybdenum reported by producers as shipments for export from the United States

(Thousand pounds contained molybdenum)

Product	1971	1972
Molybdenite concentrate	31,513	34,390
Molybdic oxide	12,292	14,577
All other primary products	1,718	1,541

Ferromolybdenum valued at $1.2 million was exported to 15 countries; Sweden and West Germany received 41% of total shipments. Exports declined for the second consecutive year.

Other molybdenum materials exported included metal, alloys in crude form, scrap, wire, powder, and semi-fabricated forms. Total value of this material was reported in excess of $2.9 million, or 4% over that exported in 1971. Although the nation is self-sufficient in molybdenum materials, some concentrate, molybdenum products, and chemicals enter the United States from numerous countries throughout the free world. High tariff rates preclude the importation of such material in large quantities. Import duties negotiated under the 1967 "Kennedy Round" of Tariff Negotiations effective January 1, 1973, are shown in table 9.

According to the U.S. Department of

[2] Duty on waste and scrap temporarily suspended.

Commerce, imports for consumption of molybdenum materials included concentrate, waste and scrap, wrought metal, and chemical compounds. Total value of these products was reported at $1.6 million, or about 34% less than 1971 imports.

Molybdenum concentrate containing 384,811 pounds of molybdenum and valued at $543,564 was received from four countries, namely, Peru, Canada, Chile, and Mexico. Peru supplied nearly one-half of the imports. The molybdenum content of waste and scrap imported from five countries totaled 116,273 pounds valued at $223,518. West Germany, the Netherlands, and United Kingdom supplied 97% of the shipments. Imports of 23,447 pounds of molybdenum contained in wrought metal products were received from seven countries. Austria and the United Kingdom were the principal suppliers.

Molybdenum chemicals and related materials entering the United States included molybdenum compounds, inorganic compounds, molybdenum orange, and ammonium molybdate. Imports of molybdenum compounds totaling 1,758 pounds contained weight and valued at $11,109 were received from two countries. West Germany supplied most of the material. Four countries exported molybdenum orange to the United States. The gross weight of the material totaled over 1.3 million pounds valued at $484,173. Canada and Japan supplied about 65% of the total value. Inorganic compounds and ammonium molybdate were imported to the United States from two countries and totaled 24,130 pounds contained weight valued at $120,715.

[1] In addition to the countries listed, Argentina, North Korea, Nigeria, Romania, South-West Africa, and Spain also may produce molybdenum, but information is inadequate to make reliable estimates of output levels.

WORLD REVIEW

Australia.—Minefield Exploration Ltd. continued geological investigation of its Mt. Mulgine molybdenum prospect in Western Australia. The company was spending $300,000 for exploration purposes and reportedly was no longer seeking a partnership arrangement in developing the property. In 1971, the company discovered a complex mineral deposit estimated at 118 million tons of ore containing molybdenum, copper, gold, silver, and bismuth.

Canada.—Molybdenum production increased about 2.2 million pounds in 1972 and was nearly 10% over that of 1971. About one-half of Canadian output came from byproduct plants. Canada consumes about 6% of its production; hence, as in the United States, Canada depends on export markets to maintain a viable molybdenum mining industry. Because of a continued worldwide oversupply of the material, some mines were closed, some curtailed production, and some byproduct plants did not recover molybdenum during the year. Molybdenum in stock at various plant sites was estimated in excess of 20 million pounds at yearend. Despite an oversupply situation and mounting inventories, new byproduct mining facilities came onstream and an active exploration program discovered new molybdenum prospects during the year.

A number of geological reports describing molybdenum deposits in Canada and the western Cordillera of North America were published.[3]

Endako Mines Ltd., owned by Placer Development Ltd., reduced molybdenum output from 14.4 million to about 9 million pounds annually during the first quarter 1972. It was the second cutback in production in less than a year; the firm dropped molybdenum output 25% in August 1971. The additional reduction was necessary because of mounting inventories due to depressed markets in Japan and Europe. The company's accumulation of unsold molybdenum in concentrate reportedly was nearly 8 million pounds at yearend. Approximately 75 employees of the total work force of 420 were terminated because of the production curtailment. During 1972, the mill treated nearly 6.4 million tons of ore at an average grade of 0.149% molybdenum disulfide. On the basis of operating days, the concentrator processed 24,150 tons per day. The metallurgical recovery was 81.2%. The roaster operated at maximum capacity throughout the year. Enlargement of the roasting capacity was contemplated in order to meet an increasing demand for molybdic oxide.

Clark, K. F. Stockwork Molybdenum Deposits in the Western Cordillera of North America. Econ. Geol., v. 67, No. 6, September–October 1972, pp. 731–758.

Ney, C. S., J. M. Anderson, and A. Panteleyev. Discovery, Geologic Setting and Style of Mineralization, Sam Goosly Deposit, British Columbia. Can. Min. and Met. Bull., v. 65, No. 723, July 1972, pp. 53–64.

British Columbia Molybdenum Ltd., subsidiary of Kennecott Copper Corp., ceased operations at its molybdenum mine and mill facility near Alice Arm, British Columbia. Company officials stated that high production costs and a weak molybdenum market was the cause for the shutdown. The mine commenced production at yearend 1967, but operations were plagued with mining problems and high costs. For the past 4 years of operations 1968–1971, the mine produced nearly 22 million pounds of molybdenum.

Molybdenite Corp. of Canada Ltd. finally closed the Lacorne mine and mill in September. The operation located in northwestern Quebec was financially assisted for the past year by the provincial government to arrest the economic impact in the area due to its closing. In early 1971, the mine was temporarily closed because of marketing problems for molybdenite concentrate.

Red Mountain Mines Ltd., near Rossland in south-central British Columbia, suspended operations early in the year.

Utah International Inc. reached full production capability early in the first quarter at its Island Copper mine near Port Hardy on Vancouver Island, British Columbia. The deposit contains reserves estimated at 280 million tons of copper-molybdenum ore averaging 0.52% copper, 0.014% molybdenite, and significant rhenium values. The concentrator was designed to process about 12 million tons of ore annually, yielding 230,000 tons of copper concentrate and 1,500 tons of molybdenite concentrate. The grinding circuit, consisting of six large autogenous mills, each 32 feet in diameter and 14 feet long, is the largest in the world. Each mill uses 7,000 connected horsepower and has a grinding capacity of 240 tons of ore per hour.

Gibraltar Mines Ltd., owned principally by Placer Development Ltd., commenced concentrator operation in March on ore stockpiled from the recently developed open pit copper-molybdenum mine. The facility, located near McLeese Lake in the Cariboo district of British Columbia, was designed to process about 11 million tons of ore annually from which 100 million pounds of copper and about 2.5 million pounds of molybdenum will be recovered. Total reserves contained at four open pit operations were reported at 358 million tons, having an average grade of 0.373% copper and 0.016% molybdenite. Capital expenditures for development of the mineral deposit was reported at $68 million, or about 10% below estimated costs. The operational staff at the mine and mill facility totaled 350 persons. At yearend, the company authorized expenditures of $4.8 million for purchasing additional ore production, haulage, and related equipment. Deliveries of the equipment will be made over a 3-year period to coincide with new pit development. The mining rate was revised to provide greater flexibility and efficiency in meeting the concentrator requirements. A report describing the unique operation was published.[4]

Lornex Mining Corp. Ltd., managed by Rio Algom Mines Ltd., commenced production at an open pit copper-molybdenum mining facility near Logan Lake, British Columbia. The concentrator was designed to process about 14 million tons of ore annually from which 110 million pounds of copper and about 2.5 million pounds of molybdenum will be recovered. First shipments of copper concentrate were made during the second quarter 1972 by way of truck to Ashcroft, thence, by railroad to Vancouver for transshipment to foreign markets. The company negotiated a 12-year sales contract consigning the copper concentrate output to Japanese smelters, and molybdenum production for 5 years was sold to Philipp Brothers Co., a metal dealer in New York. Capital expenditures for development of the copper-molybdenum deposit was reported at $138 million. Construction of the facility, largest open pit base metal mine in Canada, was completed in less than 2 years. A work force totaling 550 persons was employed at yearend. Operations of the Lornex Mining Corp. Ltd. were described.[5]

Gaspé Copper Mines Ltd., owned by Noranda Mines Ltd., was spending $108 million for expansion of mine, mill, and smelter capacity and construction of new sulfuric acid and leaching plants. Mine production of copper-molybdenum ore was expected to increase to nearly 34,000 tons per day; 30,000 tons will be supplied from the Copper Mountain open pit mine, and the remainder from Neddle Mountain underground operation. The facility, located near Murdockville, Quebec, will have a production potential of about 2 million pounds of molybdenum annually. Ore reserves were reported totaling 25.3 million tons averaging 1.17% copper at the Neddle Mountain mine and 260 million tons averaging 0.42% combined sulfide and oxide at the Copper Mountain mine. The ores contain significant amounts of molybdenum.

[5] Western Miner. Lornex Mining Corp. Ltd. V. 45, No. 8, August 1972, pp. 35–53.

A preliminary feasibility study of Bethlehem Copper Corp. Ltd. (Canada) for its J–A copper-molybdenum deposit was reported to favor an economically viable mining operation at a rate of 25,000 tons of ore per day. The mineral deposit, containing about 300 million tons of proven ore grading 0.45% copper with significant amounts of molybdenum, was situated in close proximity to the company's Huestis open pit mine in the Highland Valley District, British Columbia. The J–A mineralization was classified as a porphyry type copper deposit, similar to other British Columbia mineral deposits. Initial development projects costing $2.5 million were authorized for relocation of roads, power lines, and a natural gas line. The company was conducting detailed engineering studies in conjunction with various consultants. Some of these investigations include mine design, plant layout, tailings disposal, reclamation programs, waste disposal, and water supply.

Highmont Mining Corp. Ltd. continued with development of a copper-molybdenum deposit in the Highland Valley district of British Columbia. At yearend, the company was negotiating sales contracts for future production. A feasibility study idicated a favorable economic operation at a rate of 25,000 tons of ore per day over a 20-year period. Ore reserves were estimated at 145 million tons having an average grade of 0.27% copper and 0.045% molybdenite.

United Asbestos Corporation was conducting exploratory drilling on molybdenite mineralization in the Gabarous Bay area of Nova Scotia. Company officials stated that several drill holes have encountered significant molybdenum values to a depth of 80 feet. Exploratory drilling and an economic evaluation of the deposit was intensified at midyear. The mineral investigation was conducted under an option agreement with Louisbourg Mines Ltd., owner of the property.

Chemalloy Minerals Ltd. acquired a major interest in a promising molybdenite deposit near Jellcoe, northeastern Ontario. Assays of some drill samples were reported to range in grade from 0.07% to 1.12% molybdenite.

Chile.—Corporación del Cobre (CODELCO), the Chilean State Copper Corp., was constructing a plant to recover molybdenum, rhenium, and other precious metal from copper ores produced at the Rio Blanco mine. The facility was expected to cost about $2.6 million. Rio Blanco was developed by the Cerro Corp. and was nationalized in 1971 by the Chilean Government.

Empresa Nacional de Minera (ENAMI), a Chilean Government agency for mineral development, reported that exploration activity continued at the Los Pelambres mineral deposit near Coquimbo, Chile. To date, drilling has resulted in outlining ore reserves totaling 400 million tons containing 0.8% copper with significant amounts of gold, silver, and molybdenum. An access road was being built in preparation for developing the huge deposit.

Egypt, Arab Republic of.—A significant molybdenum prospect was discovered in southeastern Egypt, about 60 miles east of Aswan. Two exploration holes were drilled to a depth of about 250 feet, and assays for a 125-foot section reportedly averaged 0.5% to 0.6% molybdenite. The exploration project was sponsored by a United Nation Development Program (UNDP). Additional funds totaling $2.3 million were authorized to evaluate the deposit; UNDP provided $1.1 million, and Egypt, the remainder.

Greenland.—Greenland Exploration Management Inc. acquired a 3-year exploration concession covering 12,850 acres near Godthab, from the Government of Denmark. The company geologists were reported investigating an outcrop of skarn (metamorphic rock) containing molybdenum and other metallic minerals.

Iran.—A $400 million contract was awarded to Parsons–Jurden Corp., U.S.A. for development and/or construction of a mine, concentrator, and smelter complex near Kerman. The project is based on the Sar-Cheshmeh mineral deposit reportedly containing 393 million tons of ore averaging 1.2% copper with significant molybdenum values to justify its recovery. The mine was expected to produce at a rate of 42,000 tons of ore per day. Completion of the project was scheduled for 1977.

Japan.—The construction of a molybdenum roasting plant by Japan Molybdenum Co. was delayed because of foreign exchange conditions and a continued decline in molybdenum requirements that have adversely affected the supply of investment capital. Planned capacity of the plant was 55,000 pounds of technical-grade oxide daily. AMAX was expected to contribute one-third of the plant's cost of construction.

Taiyo Mining & Industrial Co., a producer of molybdenum products and ferroalloys, obtained an exclusive license to a hydrometallurgical process from Molycorp for production of molybdenum and rhenium compounds. The process is unique in that high-purity compounds are produced from low-grade molybdenum disulfide concentrate.

Mexico.—Asarco and Cía. Mexicana de Cobre S.A. were investigating a copper-molybdenum deposit near La Caridad containing reserves estimated at 600 million tons averaging 0.8% copper and 0.016% molybdenite. A mine processing 28 million tons of ore annually was contemplated.

Netherlands.—At yearend, AMAX commenced operation of an ammonium molybdate and purified molybdic oxide conversion plant at Rozenburg near Rotterdam. The facility employs a new AMAX process to produce a complete range of high-purity molybdenum and derivative products for use in petrochemical and metallurgical industries. The highly automated plant was designed and constructed by Tebodin, NV, a Dutch firm.

Panama.—Canadian Javelin Ltd. continued drilling on a vast copper-molybdenum mineralized deposit in the Cerro Colorado concession near Boquete. More than 90 drill holes totaling over 45,000 linear feet were completed, but the extent of the ore body was undetermined at yearend. Several drill holes bottomed out in copper-molybdenum mineralization at depths to about ½ mile. Data on ore reserves were incomplete, but the ore body was reportedly estimated to contain 2.2 billion tons at a grade of 0.8% copper with significant amounts of molybdenite. Current exploration drilling was concentrated on an enriched zone containing an estimated 65 million tons of ore with an average grade of ore of over 1% copper.

The Cerro Colorado deposit is situated 32 miles from the Pacific Ocean. The company started construction of a 24-mile road from the Inter-American Highway System that parallels the Pacific coast in the area. A report describing the deposit was published.[6]

A feasibility study was contracted to Wright Engineers Inc. of Vancouver. Company officials expect the study to recommend a mining operation on the order of 30,000 to 35,000 tons of ore per day. The concentrate would be delivered by pipeline to a newly constructed Pacific coast port from whence it would be shipped to foreign markets.

Peru.—Development of the Cuajone copper-molybdenum deposit and construction of ancillary facilities by Southern Peru Copper Corp. (SPCC) was continued during the year. Work projects completed were site preparation for a concentrator and company town, 19.6 million tons of overburden stripped, and 11,450 feet of railroad tunnel mined. Expenditures totaled $82.6 million to date, of which $37 million was obligated in 1972. Compañía Constructura Utah S.A., subsidiary of Fluor Corp., U.S.A., was awarded the contract to conduct engineering, construction, and management on the project. SPCC continued negotiating with an international consortium of banks for financial assistance in developing the Cuajone deposit.

The Cuajone mine was expected to produce at a rate of 30,000 tons of ore per day. Ore reserves were reported at 468 million tons of ore, having an average grade of 1% copper with significant values of molybdenum to justify recovery.

Empresa Minero del Peru (Mineroperu) signed an agreement with a group of five Japanese copper smelting corporations to spend $2 million on a feasibility study of the vast Michiquillay copper-molybdenum deposit in northern Peru. A favorable report would result in the formation of a consortium of multinational companies that would provide the $250 million financing for development of the deposit. Asarco geologists discovered the deposit during the early 1960's, and the company reportedly spent $10 million over a 10-year period on exploration. Ore reserves were estimated at 570 million tons averaging 0.72% copper with sufficient molybdenum to justify recovery.

[6] Lutjen, G. P. Canadian Javelin Eyes Production at Major Copper Find in Panama. Eng. and Min. J., v. 173, No. 12, December 1972, pp. 60–63.

Turkey.—Etibank Ltd. was granted an exploration license to prospect for molybdenum in the Orhaneli district of Bursa. Exploration rights in the area were formerly held by Turk Molipten.

TECHNOLOGY

The effect of surface pretreatment and the role of hydrogen, hydroxyl, molybdate, and calcium ions on the flotation of molybdenite were investigated using a Hallimond tube, contact angle measurements, electrokinetics, and electrode potential measurements, and the results were described.[7] The experimental results were analyzed in terms of the Derjaguin model of wettability. The flotability of molybdenite was found to be strongly affected by surface oxidation primarily because of the effect of the oxidation on electrical and hydration phenomena.

A report describing operations of a hydrometallurgical plant in recovering molybdenum from mixed oxide and sulfide ores was published.[8] The feed material consisting of tailings from sulfide flotation was upgraded by cycloning and then leached in a sulfuric acid solution. Activated charcoal was added that absorbed the molybdenum. The charcoal was separated from the pulp and then ammoniated. The oxide molybdate was washed from the charcoal, and the liquid evaporated until all ammonium dimolybdate crystallized out. From a feed grade of only 0.12% to 0.14% molybdenum, a product containing 99.8% molybdenum trioxide was obtained.

An experimental study was made to evaluate the performance of column flotation versus conventional flotation on the recovery of molybdenite from a Newfoundland ore.[9] The investigation included a factorially designed series of tests to determine satisfactory operating conditions of the column. In the course of the experiment, the results of a few depressants also were evaluated. Results indicated greater selectivity in the column and reduced reagent consumption.

The microstructure, hardness, and superconducting transition temperature of high-purity molybdenum-ruthenium alloys were investigated.[10] Optical and electron microscopy permitted the morphology and crystallography to be analyzed. An intermetallic compound was precipitated from a supersaturated liquid having angular particles. The hardness of the alloy was determined and deformation studied. The intermetallic phase showed little evidence of plastic deformation, and only brittle fractures were observed. The phase had a superconducting transition temperature in the "as-cast" condition.

Auger electron spectroscopy was used to determine surface concentration of molybdenum in certain types of stainless steel, and the results were described.[11] It was observed that certain thermal treatments will concentrate impurities at a free surface. In some steel, sulfur was observed to concentrate at the surface at a temperature of 330° C. Surface concentration of 14% was observed in mill-finished steel containing 1.95% molybdenum and one other steel containing 0.45% molybdenum.

The high temperature creep behavior of polycrystalline molybdenum was investigated at 1,720° C, using constant stress in an ultrahigh vacuum environment.[12] The strain dependence of the dislocation substructure was studied using the etch pit technique and transmission electron microscopy. Subboundaries were formed in the transient area of the creep curve. Grain growth occurred during testing, and this phenomena was evaluated in terms of deviations from parabolic time law behavior.

[12] Ericksen, R. H., and G. J. Jones. Analysis of Primary Creep of Molybdenum at High Temperatures. Met. Trans., v. 3, No. 7, July 1972, pp. 1735–1741.

The rate of solution of molybdenum in molten iron saturated with carbon was described.[13] A rotating cylindrical molybdenum specimen was placed in a stationary graphite crucible containing an iron-base melt. Weight changes were measured to determine the solution rate in temperatures ranging from 1,315° C to 1,425° C. Theoretical and experimental correlations also were compared with the solution rate coefficient. Molybdenum diffusion in the liquid phase was observed to be rate limiting. The solution of molybdenum rod specimens in carbon-saturated liquid iron was found to be controlled by diffusion of molybdenum in the iron-carbon melt and can be predicted by a boundary-layer model.

Steel compositions were designed for application in the powdered metal forging process on the basis of new hardenability data.[14] Thirty-three steel compositions were prepared by normal casting and forging techniques to provide bar stock for the Jominy hardenability test. The steels contained varying combinations of 0% to 0.8% manganese, 0% to 0.8% nickel, 0% to 0.75% copper, and 0% to 0.75% molybdenum. Molybdenum was found to be the most effective element in imparting hardenability to carbon steel.

Dislocation interstitial interactions in high-purity molybdenum were investigated by means of internal friction measurements, and the results were described.[15] In some grades of molybdenum, a maximum was observed in the amplitude-dependent damping. The damping maximum appeared after annealed samples were deformed at room temperature and was attributed to the motion of dislocations produced by deformation. A reduction in damping observed at temperatures above 100° C was due to the diffusion of interstitial nitrogen atoms to dislocation lines.

The impact properties of high-tensile-strength steels were evaluated in relation to the cooling rate and the austenite grain size.[16] It was determined that the optimum cooling rate for the impact transition temperature varied with the hardenability of the steel. Also, the optimum cooling rate shifted to a slower cooling rate as the austenitizing temperature was increased. An electron microscopic study revealed that the structure with superior impact properties was a duplex martensite-bainite structure. The results suggest that the role of bainite in the duplex structure was the partitioning of austenite grains prior to the martensite transformation.

Patents were granted for upgrading byproduct molybdenite flotation concentrate from low-grade copper porphyry ore,[17] for the production of molybdenum trioxide and sulfur as a byproduct from molybdenite concentrate,[18] for the hydrometallurgical recovery of molybdenum,[19] for purifying roasted molybdenite of iron, lead, and zinc,[20] for removal of copper and lead impurities from molybdenite,[21] for recovery of molybdenum and rhenium from a solution obtained by leaching roasted molybdenum ores,[22] and for purification of lead containing molybdic oxide.[23]

Natural Gas

By William B. Harper [1] and Leonard L. Fanelli [2]

Natural gas consumption in 1972 was only slightly above that of 1971. Pipeline transmission companies were compelled to curtail sales to industrial consumers. However, these curtailments were slightly more than offset by increases in residential and commercial uses. Total natural gas used in 1972 amounted to nearly 23 trillion cubic feet, or nearly 1.5% over that of 1971. Production totaled 22.5 trillion cubic feet in 1972, a volume only 38.7 billion cubic feet or 1% higher than that of 1971, as shown in table 1. Pipeline imports passed the 1 trillion-cubic-foot milestone in 1972, rising to 1,019 billion cubic feet, a 9.1% increase. Canada accounted for all but 1% of imports in 1972. In addition, 674,000 barrels of liquefied natural gas (LNG), equivalent to 2,261.5 million cubic feet (MMcf), were imported from Algeria and Canada.

Approximately 30 billion cubic feet of natural gas was exported by pipeline, of which 52% was moved to Canada by pipeline. Mexico received 14.6 billion cubic feet or 48% also by pipeline. In addition, 47.9 billion cubic feet of LNG was exported to Japan from Alaska during 1972.

Proved reserves of natural gas declined again as withdrawals (production) exceeded, by a wide margin, additions to reserves from new discoveries and extensions of known fields. Also, previous estimates of reserves were revised downward drastically, particularly in Texas.

The average value of natural gas at the well inched upward 0.4 cents from 18.2 cents to 18.6 cents per thousand cubic feet (Mcf).

Some 604,000 new residential users of natural gas were added, raising the total to 39,871,000 by the end of 1972, for an increase of 1.5%. The use of gas by residential clients increased 3.0%.

Pipeline networks expanded in 1972. Some 16,500 miles of line were added primarily in the distribution category. Capital expenditures for new plants and equipment rose from $2,419 million in 1971 to $2,822 million in 1972. Construction of new synthetic gas plants using liquid hydrocarbons, such as naphtha for feedstocks, are progressing slowly. One such plant, designed to operate seasonally, has been completed, and two similar plants are expected to start up early in 1974. At the end of 1972, there were three plants under construction.

Coal gasification received additional impetus as the result of an agreement between the Department of the Interior and the American Gas Association (AGA) to jointly finance a research program that will cost about $120 million over a 4-year period. This project is being funded through the Department of the Interior's Office of Coal Research.

Inability to obtain additional gas supplies has created problems for both the transmission companies and the distributors. Firm volume curtailments for the 1972–73 winter season, reported by 14 pipeline transmission companies, totaled 565.6 billion cubic feet according to the Federal Power Commission (FPC).

Legislation and Government Programs.—Federal Power Commission (FPC) Area Rate Proceedings:

South Louisiana Area.—Subsequent to the issuance by the FPC of Opinion 598 establishing base area rates in the South Louisiana Area, the Commission issued another opinion, Opinion 598-A, on rehearing in September 1972. Arguments were heard in October 1972, and since then the Fifth Circuit Court has affirmed FPC Opinion 598 which accepted the United Distribution Companies (UDC) Settlement Proposal in the second South Louisiana Area

[2] Survey statistician, Division of Fossil Fuels.

Rate Proceeding (AR 61–2 et al, AR 69–1).[3]

Other Southwest Area.—The FPC Opinion 607 determined rates in the area[4] ranging from 19.4 cents to 20.6 cents per Mcf for gas produced under contracts dated before October 1, 1968. For production under contracts dated after October 1, 1968, rates ranged from 22.5 cents to 26.0 cents. In January 1972, the FPC issued an opinion on rehearing (No. 607-A) which included a proviso giving natural gas producers the option of meeting their refund responsibilities by the dedication of new reserves to interstate commerce. This opinion was sent on appeal to the U.S. Court of the Fifth Circuit and the Court upheld the FPC decision in Opinion 607, establishing rates for pre—1961 contracts, 1961–68 contracts, and post—October 1, 1968, "new" gas contracts. Base area rates for the three different vintages are as follows:

	Cents per thousand cubic feet (Mcf) [1]						
	First vintage gas deliveries			Second vintage gas deliveries			Third vintage gas deliveries
	Contracts dated before Jan. 1, 1961			Contracts dated Jan. 1, 1961–Sept. 30, 1968			
	Prior to Jan. 1, 1965	Jan. 1, 1965 to Sept. 30, 1968	From Oct. 1, 1968	Prior to Jan. 1, 1965	Jan. 1, 1965 to Sept. 30, 1968	From Oct. 1, 1968	Contracts dated after Oct. 1, 1968
Other Oklahoma	17.5	18.4	19.4	18.4	18.9	19.4	23.75
Texas District 9	17.8	18.7	19.7	18.7	19.2	19.7	24.0
Northern Arkansas	17.0	17.9	18.8	17.8	18.3	18.8	23.0
Texas District 5	(2)	(2)	(2)	(2)	(2)	(2)	23.5
Texas District 6	15.0	17.0	19.1	18.1	18.6	19.1	23.5
North Louisiana	16.7	18.6	20.6	19.6	20.1	20.6	25.0
Southern Arkansas	14.4	16.25	18.25	17.25	17.25	18.25	22.5
Mississippi-Alabama	19.0	19.5	20.0	19.0	19.5	20.0	25.0
Mississippi offshore (Federal Domain)	(3)	(3)	(3)	(3)	(3)	(3)	26.0

[1] Prices stated at 15.025 psia in North Louisiana, Mississippi, and Alabama, and at 14.65 psia in all other areas.
[2] No jurisdictional contracts dated prior to Oct. 1, 1968.
[3] No production to date from offshore Mississippi.

In addition, FPC Opinion 607 provided for the following: (1) A 1 cent escalation in rates for all vintages of gas effective October 1, 1973 (October 1, 1974, in the case of offshore Mississippi); (2) except for these fixed escalations, a moratorium to July 1, 1976, on further price increases; (3) deductions ranging from 1.0 cents to 1.5 cents, depending on subarea, for ungathered gas; (4) quality standards and price adjustments for quality; and (5) refund of all amounts collected subject to refund in excess of the applicable area rates.

Subsequently, in Opinion 607-A, the FPC authorized a refund workoff procedure similar to that established by its decisions in the South Louisiana and Texas Gulf Coast Area cases. Specifically, the FPC provided that producers could apply a credit of 1 cent for each Mcf of new gas reserves in the Other Southwest Area dedicated to interstate pipelines from the date of the instant order through January 1, 1976.

Appalachian and Illinois Basin Areas.—Four natural gas companies operating in the Northeastern United States filed a petition in January 1972, asking that ceiling rates for gas purchases from the Appalachian Basin be increased to at least 50 cents per Mcf. Faced with a severe shortage of natural gas, the four companies asserted that the requested increase would stimulate exploration and development and would result in new reserves for the northeast market area.

Permian Basin Area (AR70–1 Permian II).—This proceeding was initiated on July 17, 1970, at the same time as the FPC's R-389 rulemaking proceeding to establish new ceiling rates for the certification of new contracts in the Permian Basin Area. In December 1972 an FPC judge recommended a 35-cent ceiling on

---

[3] FPC Opinion 598 and the UDC Settlement Proposal are discussed in detail in the Natural Gas chapters of the Bureau of Mines Minerals Yearbook 1970 and 1971 editions.

[4] Includes Mississippi; Arkansas; four counties in northwest Alabama; northern Louisiana; Texas Railroad Commission Districts 5, 6 and 9; and 56 counties in eastern and southeastern Oklahoma.

Table 1.—Salient statistics of natural gas in the United States

	1968	1969	1970	1971	1972
Supply:					
Marketed production [1] million cubic feet	19,322,400	20,698,240	21,920,642	22,493,012	22,531,698
Withdrawn from storage do	1,329,536	1,379,488	1,458,607	1,507,630	1,757,218
Imports do	651,885	726,951	820,780	934,548	1,019,496
Total do	21,303,821	22,804,679	24,200,029	24,935,190	25,308,412
Disposition:					
Consumption do	19,459,939	20,922,800	22,045,799	22,676,581	23,009,445

[1] Marketed production of natural gas represents gross withdrawals less gas used for repressuring and quantities vented and flared.

base area rates for sales under contracts dated October 1, 1968 and later, and 19.5 cents per Mcf for sales dated prior to October 1, 1968. Subsequently, the FPC issued Opinion 662 substantially adopting the initial decision (issued December 20, 1972) by FPC Judge Nahum Litt in the second Permian Basin Area Rate Proceeding (AR70–1). The Commission approved his recommendation of a base area rate of 35 cents per Mcf for sales under contracts dated October 1, 1968, and later, but granted a flowing gas rate of 23 cents per Mcf, which includes an additional 3.5 cents per Mcf above the 19.5-cent rate recommended by the FPC judge for exploration and development, for sales under contracts dated prior to October 1, 1968. In addition, the Commission agreed with the FPC judge's approval of fixed escalations of 1 cent in base ceiling rates, on October 1, 1974, for pre-October 1, 1968, contracts and on October 1, 1975 for post-October 1, 1968 contracts.

Other recommendations of FPC Judge Litt approved by the Commission include the following: (1) Contingent escalations in rates under pre-October 1, 1968, contracts upon dedication of specified quantities of additional Permian Basin reserves to interstate commerce over the next 5 years, 0.5 cent for commitment of 4 trillion cubic feet, a further 0.5 cent for a total of 8 trillion cubic feet, and another 1.0 cent for a total of 12 trillion cubic feet; (2) a refund credit procedure enabling producers to discharge their refund obligations through dedication of additional gas reserves in the Permian area to interstate buyers (at the rate of 1.0 cent for each Mcf dedicated) over the 5-year period to January 1, 1978; (3) application of base area rates according to the date of discovery, rather than contract date, for production from newly discovered reservoirs on previously committed acreage; and (4) continuation of the quality standards and adjustments (except involving the British thermal unit (Btu) adjustment noted below) imposed in the first Permian case.

Opinion 662, however, modified the FPC judge's decision in the following respects: (1) It eliminated the 5-year moratorium on above-ceiling rate increases; (2) it increased from 1.0 cent to 1.5 cents the allowance for substantial offlease gathering (but eliminated a 0.5-cent increase on January 1, 1978; (3) it increased the minimum rate from 12.0 cents to 15.0 cents per Mcf; (4) it eliminated the Btu adjustment gap of 1,000 to 1,050 Btu; and (5) it provided for an adjustment to reflect 87.5%, rather than 75%, of any change in State or Federal production, severance, gathering, or similar taxes.

Sales, Small Producers.—Producers selling less than 10 billion cubic feet of natural gas annually and not affiliated with pipelines were relieved of complying with producer rates and certificate regulations by FPC Order 428, issued March 18, 1971. On December 12, 1972, however, the U.S. Court of Appeals for the District of Columbia circuit, reversed FPC Order 428, holding that the Order exceeded the FPC's authority under the Natural Gas Act.

Small producers account for about 15% of the interstate gas sales and comprise an important source of nonassociated gas discoveries even though production activities are relatively small.

Pipeline Safety.—Based on failure reports from which table 2 was developed, the Office of Pipeline Safety (OPS) estimated that 70% of the gas distribution incidents and 50% of the transmission line failures during the last 3 years, resulted from outside force damage. In January 1972, OPS sent to key officials of State and local governments and others concerned with damage problems, a proposed model statute to be enacted in order to reduce damage to buried pipelines and utilities which can result during underground construction work. Five amendments to the Federal safety standard, established under the Natural Gas Pipeline Safety Act of 1968, were issued in 1972.

One amendment extended the effectivity of interim Federal safety standards applicable to gas odorization in States requiring odorization in transmission lines.

Several serious gas explosion incidents, resulting from the unauthorized introduction of natural gas into inactive gas service lines, demonstrated a clear need for more stringent requirements to prevent such occurrences. An amendment was added to prevent unauthorized persons from activating gas service lines that have been deactivated, abandoned, or not presently in use.

An amendment, which modified the restrictions on accidental pressure buildup in certain pipelines other than low-pressure distribution systems, was issued. This amendment should provide more realistic pressure relief limitations.

Aware of the rapid growth in construction and operation of facilities to transport and store liquefied natural gas (LNG), the OPS in the Department of Transportation issued an amendment adding a new section to the Federal Safety Standards applicable to those gas pipeline facilities used to store, treat, or transfer LNG.

Another amendment was issued on October 11, 1972, which allows permanent field repair of pipeline leaks on certain lower pressure transmission lines.

DOMESTIC PRODUCTION

Gross production of natural gas represents the total amount of gas produced, including marketed production of gas, gas returned to the formation for pressure maintenance, and the gas vented or flared. In 1972, gross production aggregated nearly 24.0 trillion cubic feet or slightly below the almost 24.1 trillion cubic feet produced in 1971.

A 4% decline in the gross production of gas from oil wells, from 5.2 trillion to 4.9 trillion cubic feet, more than offset an increase of 117 billion cubic feet of gas withdrawn from gas wells. Increased gross production was noticeable primarily in five States. In New Mexico, Oklahoma, and Texas withdrawals of natural gas were moderately higher. Significant gains, however, were made in the smaller gas producing States of Alabama and Florida. Availability and the startup of new natural gas processing plants in which sulfur recovery units are incorporated, were the prime causes for these production increases. Much of the natural gas in this region has a high sulfur content. Higher prices for gas, however, provided an incentive to extract the sulfur so that the gas would be acceptable for pipeline transmission. The sulfur extracted from the gas is sold to fertilizer manufacturers.

On the negative side, there were very sizable reductions in the gross withdrawals of gas in California and in Louisiana. In both instances the reductions were in the volume of associated gas withdrawn from oil wells as shown in table 3. Gas well gas withdrawals in Louisiana also decreased 87.5 billion cubic feet in 1972.

Marketed production in 1972, however, was 38.7 billion cubic feet above that of 1971, because less gas was vented and flared and less gas was used for repressuring than in 1971. In Texas, a reduction of 64.9 billion cubic feet used for repressuring made that much more gas available for market. A reduction in Louisiana of nearly 40 billion cubic feet in the volumes of gas vented or flared however was not large enough to offset the overall decline in marketed production. Marketed production in 1972 was 109 billion cubic feet lower in 1972 in Louisiana. Year to year changes are shown in table 3.

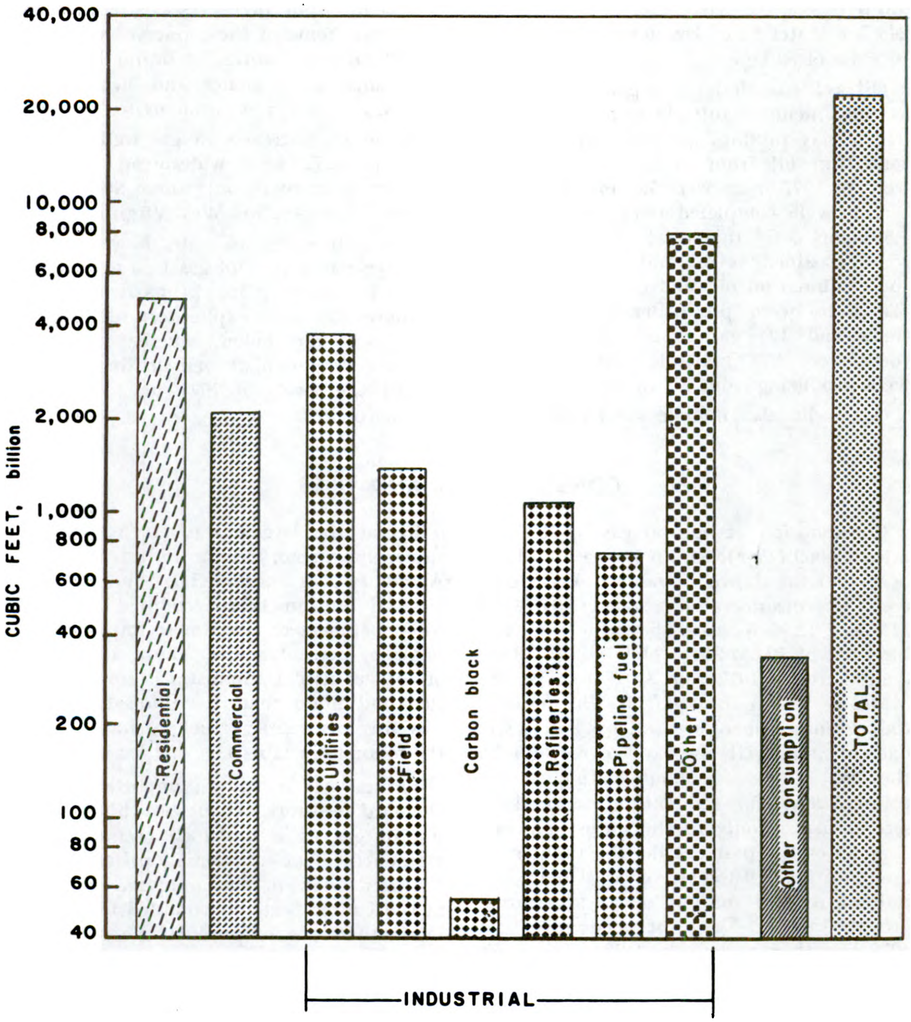

Figure 1.—Disposition of natural gas consumed in the United States by principle use.

Rising prices for naural gas and the endorsement of FPC Opinions by the Courts, relative to FPC Area Rate Proceedings, were beginning to encourage investment in gas exploration and production. During 1972, there were 4,928 gas wells drilled compared with 3,830 gas wells in 1971 or a gain of 28.7% as shown in table 4. There were, in 1972, 601 exploratory gas wells drilled as compared with 437 wells in 1971, a gain of 37.5%, and the drilling pace accelerated in 1973. A 6-year tabulation of gas and combination oil and gas well completions for gas is presented in table 5.

Higher prices for natural gas have made it economical to build natural gas processing plants with sulfur recovery units. As a result, efforts are being made to drill and explore for gas whether it be sweet or sour. This effort is noticeable in States where production has been small, such as in Alabama. Production in that State in 1972 increased tenfold; proved reserves increased from 180,508 million cubic feet

(MMcf) as of December 31, 1971, to 245,714 MMcf as of December 31, 1972, an increase of 36.1%.

Oil well completions are included insofar as they include multiple completion wells which may produce gas from one or more zones but oil from at least one zone as well. In 1972 there were 729 multiple completion wells completed and producing from 1,501 zones. Of this total, there were 799 zones classified as oil and 702 as gas. In the combination oil- and gas-well category, 120 wells were producing from 124 oil zones and 124 gas zones. Also in 1972, there were 278 multiple completion gas wells producing from 578 zones.

Gas wells also include condensate wells producing from high-pressure natural gas reservoirs. Some of these reservoirs produce considerable quantities of liquid hydrocarbons such as pentanes and heavier, described generically as "condensate."

Significant increases in gas well completions in 1972 were widespread. Reduced activity occurred in only three States: Colorado, Tennessee, and West Virginia.

It is interesting to note, however, that the accelerated pace of gas well drilling activity is taking place primarily onshore. Offshore gas well exploratory drilling in 1972 was far below activity in 1971. Offshore development well drilling did not exceed the levels of 1971 until the final quarter of 1972.

CONSUMPTION AND USES

Consumption of natural gas in 1972 totaled 23,009,445[r] MMcf, an increase of 1.5% over 1971, as shown in table 6. Gas delivered to consumers aggregated 19,879,733 MMcf, a 1.2% increase above the comparable total of 19,637,212 MMcf in 1971. Residential use in 1972 rose 3.1%, to 5,125,982 MMcf as shown in table 11. The residential consumption of natural gas ranks second to industrial use, and expansion in the use of gas for househeating is the prime reason for residential use, ranking second in size only to the industrial category. Over the past decade, the number of househeating customers grew from 23.6 million to 32.9 million or at an annual growth rate of 3.4%. Between 1971 and 1972 growth contracted to 2.7%. Trends in the number of househeating accounts by Census Regions for the years 1962, 1971, and 1972 are indicated in the following tabulation:

Census regions	Gas househeating customers (Thousands)		
	1962	1971[r]	1972
New England	490	785	817
Middle Atlantic	2,804	3,801	3,897
East North Central	5,273	7,837	8,056
West North Central	2,253	3,033	3,090
South Atlantic	1,813	2,800	2,889
East South Central	1,324	1,779	1,813
West South Central	3,684	4,374	4,444
Mountain	1,253	1,783	1,889
Pacific	4,701	5,902	6,068
Total	23,595	32,094	32,963

[r] Revised.

Source: American Gas Association.

By far the largest segment in the consumer-use category is the industrial group. About 14% is consumed by industry. Industrial uses in 1972 accounted for 8,167 billion cubic feet, an almost imperceptible increase, percentagewise, above 1971. Most of the gas used by industry is consumed as fuel and more than 1 trillion cubic feet was used as refinery fuel as indicated in the footnote in table 11.

Natural gas is also an important petrochemical feedstock. About two-thirds of the use of gas as a feedstock occurs in the manufacture of ammonia, primarily for fertilizer. Most of the ammonia produced in the United States is obtained by reforming natural gas to produce the hydrogen-nitrogen mix required for ammonia synthesis. It is estimated that, on the average, the natural gas consumed per ton of ammonia was about 37 Mcf. This would mean that more than 435 billion cubic feet of natural gas was used to produce 11.7 million tons of synthetic ammonia in 1972. Methanol production is another important consumer of natural gas. There were nearly 3,000,000 short tons of methanol produced in 1972. Using 36 Mcf per short ton as a yardstick, it is estimated that 108 billion cubic feet of natural gas was consumed in methanol production. Carbon black production accounted for another 54 billion cubic feet. It is estimated that the chemical industry consumed nearly 900 billion cubic feet of natural gas or 11% of the total industrial use, as shown in table 11.

The uptrend in the consumption of natural gas by the electric utilities was reversed in 1972 when use was down slightly (to 14,310 Mcf) as increases in the west, southwest, and west coast States were not large enough to offset declines in the midwestern and eastern States.

There was only a slight increase in the number of commercial consumers in 1972—from 3,341,000 to 3,357,000 consumers, or less than 0.5%. Use of gas in this category, however, increased to 2,286,561 MMcf from 2,172,699 MMcf, or 5.2%.

In addition to gas delivered to consumers, there are three categories of gas-use separately classified in table 6: lease and plant fuel, pipeline fuel, and extraction losses. Gas used as lease and plant fuel (oil and gas field use) increased nearly 3%. Likewise, gas used as pipeline fuel increased 3%. The loss of gas in gas processing plants (shrinkage) increased 2.8% in 1972 as shown in table 7. In 1972, these plants processed 19,947,740 MMcf of natural gas (88.5% of marketed production), an increase of 3.6% over the 19,252,807 MMcf processed in 1971.

Although there has been a marked growth in natural gas use ever since long-distance natural gas transmission lines became a reality, the tight supply situation is becoming more and more critical for pipeline transmission companies. In fact, the shortage of gas forced major interstate gas pipeline companies to curtail gas service. During the April-October 1972 season, 11 of the 32 major pipelines listed in table 8, reported firm volume curtailments aggregating almost 555.4 billion cubic feet or 10.5% of their firm requirements of nearly 5.3 trillion cubic feet of natural gas. These curtailments were 64% greater than for the comparable season a year earlier. Table 8 is based on data submitted to the FPC.

The FPC has also drafted a series of proposed priorities of deliveries based on end use in Orders No. 467 A and 467 B. A list of these priorities follows:

1. Residential, small commercial (less than 50 Mcf on a peak day).
2. Large commercial requirements (50 Mcf or more on a peak day), firm industrial requirements for plant protection, feedstock and process needs, and pipeline customer storage injection requirements.
3. All industrial requirements not specified in 2, 4, 5, 6, 7, 8, or 9.
4. Firm industrial requirements for boiler fuel use at less than 3,000 Mcf per day, but more than 1,500 Mcf per day, where alternate fuel capabilities can meet such requirements.
5. Firm industrial requirements for large volume (3,000 Mcf or more per day) boiler fuel use, where alternate fuel capabilities can meet such requirements.
6. Interruptible requirements of more than 300 Mcf per day, but less than 1,500 Mcf per day, where alternate fuel capabilities can meet such requirements.
7. Interruptible requirements of intermediate volumes (from 1,500 Mcf per day through 3,000 Mcf per day), where alternate fuel capabilities can meet such requirements.
8. Interruptible requirements of more than 3,000 Mcf per day, but less than 10,000 Mcf per day, where alternate fuel capabilities can meet such requirements.
9. Interruptible requirements of more than 10,000 Mcf per day, where alternate fuel capabilities can meet such requirements.

Relative to the question of FPC jurisdiction on curtailments, a decision by the U.S. Supreme Court on June 7, 1972, held the FPC has jurisdiction over curtailments in the service of gas in interstate commerce to both resale and direct industrial customers.[5] This decision reversed a Fifth Circuit Court ruling that immunized direct industrial customers from curtailments.

The gas-distributing utilities are taking similar steps in establishing priorities. First, new industrial and commercial accounts were curtailed. Some utilities will no longer accept any new or additional customers capable of using in excess of 10 therms per hour. An average residential househeating customer can use approximately 2 therms per hour. A therm is a unit of heating value equivalent to 100,000 Btus.

The uncertainties as to the availability of new gas supplies is also having an impact on expansion of the pipeline networks. The mileage of natural gas pipelines increased to 951,200 miles in 1972 but the rate of growth moderated with the drying up of new gas supplies, as indicated in the following tabulation:

---

[5] The U.S. Supreme Court in *FPC vs. Louisiana Power and Light Co.* 406 U.S. 621.

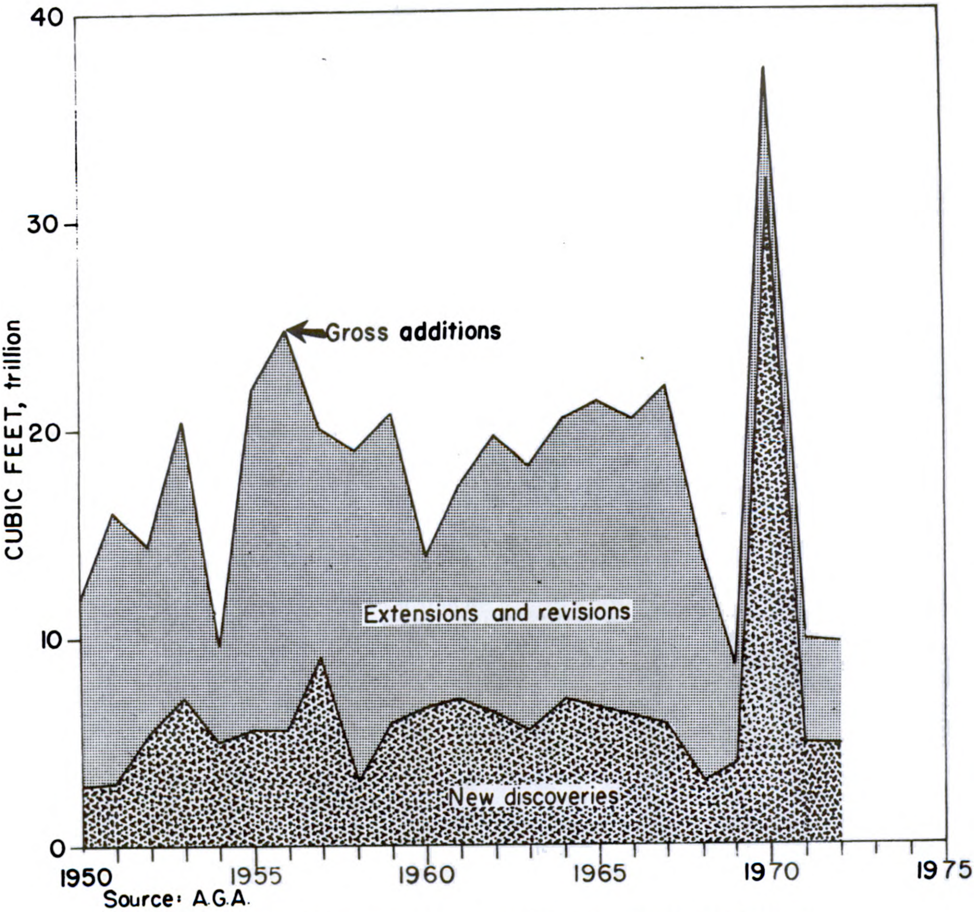
	1961	1971	1972
Field and gathering	56.7	66.5	67.1
Transmission	191.9	256.9	260.2
Distribution	410.4	611.3	623.9
Total	659.0	934.7	951.2

Some 16,500 miles were added in 1972 and distribution lines accounted for 12,600 miles of the total. Interstate movements of natural gas are shown in table 9. New interstate pipeline movements are available in table 10.

RESERVES

Production of natural gas has exceeded discoveries of new gas during 4 of the last 5 years and 1972 proved to be no exception. During 1972, production again exceeded discoveries by a wide margin and proved reserves of natural gas dropped from 278.8 trillion cubic feet at yearend 1971 to 266.1 trillion cubic feet by 1972 yearend, or a decline of 4.6%, according to the Natural Gas Reserves Committee of AGA.

Additions to reserves reported for the United States in 1972 aggregated nearly 10.8 trillion cubic feet. The largest segment, some 6.1 trillion, was derived from extensions to known fields. Second in importance was the 3.1 trillion cubic feet from new reservoir discoveries in old fields.



Source: A.G.A.

Figure 2.—Trends in annual gross additions to natural gas reserves.

More than two-thirds of the 3 trillion cubic feet came from Louisiana. In addition, discoveries of new fields totaled almost 1.5 trillion cubic feet of reserves. On the negative side, however, previous estimates of reserves in some States were revised. On balance, there was a reduction for the United States, as a whole, of nearly 1.1 trillion cubic feet as shown in table 12.

There were some increases in the reserves of natural gas in Alabama, Alaska, Illinois, Montana, Ohio, Pennsylvania, Utah, and other States which produce small amounts of gas. These net increases, however, aggregated only 688 billion cubic feet. On the negative side, reserves of major gas-producing States declined sharply. Texas gas reserves dropped from 101.5 trillion cubic feet to 95.0 trillion cubic feet, a decline of 6.4 trillion cubic feet. Likewise, in Louisiana proved reserves decreased 3.7 trillion cubic feet or 4.6% to 74.9 trillion cubic feet. Comparisons of the proved reserves as of December 31 for 1971 and 1972 are presented in table 12.

Estimated potential supply of natural gas in the United States as of December 31, 1972
(Trillion cubic feet at 14.73 psia and 60° F.)

	Probable	Possible	Speculative	Total
Report Dec. 31, 1972	266	384	496	1,146
Report Dec. 31, 1970	257	387	534	1,178
Change in report	+9	—3	+38	—32

The Potential Gas Committee (PGC) reports natural gas resources in three categories: probable, possible, and speculative. Briefly, "probable" refers to the unproved portions of existing fields; "possible" is production that will result from new field discoveries in areas of established production; and "speculative" is commercial natural gas that will result from new field discoveries in areas where sediments are present but have no prior production history. The PGC's estimate of the potential supply of natural gas in the United States, excluding the State of Hawaii, the island territories of the United States, and their adjacent offshore areas, is shown in table 13.[6]

Table 13 shows PGC's reserves estimates by hole depths and water depths for the United States.

In addition to exploration for new resources in the United States, American companies are involved, either independently or with Canadian companies, in exploring and drilling for oil and gas in Canada's Arctic Islands, the Maritime Provinces, and in the Mackenzie Delta. By the end of 1972, the delta had yielded seven bas-condensate and oil discoveries and established an impressive natural gas reserve base for Canada. These developments, plus significant natural gas discoveries in the Arctic Islands could possibly influence the National Energy Board of Canada to raise prevailing ceilings on exports of natural gas to the United States.

PRODUCTIVE CAPACITY

The daily productive capacity for natural gas at the end of 1972 was estimated to be 85,998 MMcf according to the AGA. This compares with 94,017 MMcf per day as of December 31, 1971. Productive capacity in nonassociated gas fell to 69,144 MMcf from 75,371 MMcf. Likewise, capacity in associated-dissolved gas was reduced to 16,854 MMcf from 18,646 MMcf per day as of December 31, 1971.[7] Compared with that of 1972, daily productive capacity had dropped 8 billion cubic feet or almost 8.5% by the end of 1972 as shown in table 14.

---

[6] The work by the PGC is supported by three industry associations: the AGA, the Independent Natural Gas Association of America (INGAA), and the American Petroleum Institute (API).

[7] The productive capacity of natural gas from nonassociated reservoirs is defined as the maximum daily rate at which such gas can be produced from natural reservoirs under specified conditions on March 31 of any given year. The determination of productive capacity on March 31 of any given year is based on proved reserves of nonassociated gas reservoirs as of the preceding December 31. The productive capacity of associated-dissolved gas is based on the productive capacity of crude oil and the estimated producing gas-oil ratios which would result from such capacity operation during the first 90 days of a given year. The productive capacity of associated gas from gas wells is usually based on the volumetric withdrawal of crude oil from related oil wells at capacity rates during the first 90 days of a given year as determined by the American Petroleum Institute (API) Committee on Reserves and Productive Capacity.

STORAGE

The development of additional underground storage capacity for natural gas, after slackening in 1970, moved at a faster pace in 1971 and 1972. Total reservoir capacity increased 8.3% from 5,575 MMcf in 1971 to nearly 6,040 MMcf by yearend 1972. The number of underground storage facilities expanded from 333 in 1971 to 348 in 1972. These storage facilities are located in 26 States.

Originally most of these reservoirs were depleted fields which contained dry gas. Of the 348 reservoirs, for example, 275 or 79% were the dry-gas type and, as evidenced in table 15, most of these dry-gas reservoirs are located in the northeastern United States, primarily in the oldest oil provinces. The second largest concentration is found in the midwest. In Pennsylvania, where oil production dates back to 1859, some 68 dry-gasfields have been converted to storage facilities. West Virginia added two more in 1972 and now has 33 dry-gas reservoirs. In Michigan, where oil production began on a small scale in the early 1900's, there were 30 of the dry-gas-type reservoirs as of the end of 1972.

In terms of capacity there was a net increase of 464,414 MMcf of which Illinois accounted for nearly one-quarter. Even more significant, however, is the increase in Mississippi. In 1971, there were three reservoirs in that State with 10,238 MMcf of capacity. During 1972 capacity was expanded to 108,956 MMcf and gas in storage increased sevenfold as shown in table 15.

In addition to storage underground there is a marked growth in the storage aboveground of natural gas liquefied by lowering temperatures. When natural gas is converted to a liquid by reducing its temperature to −258° F (−161° C) it occupies only 1/620th the space necessary for conventional vapor storage.

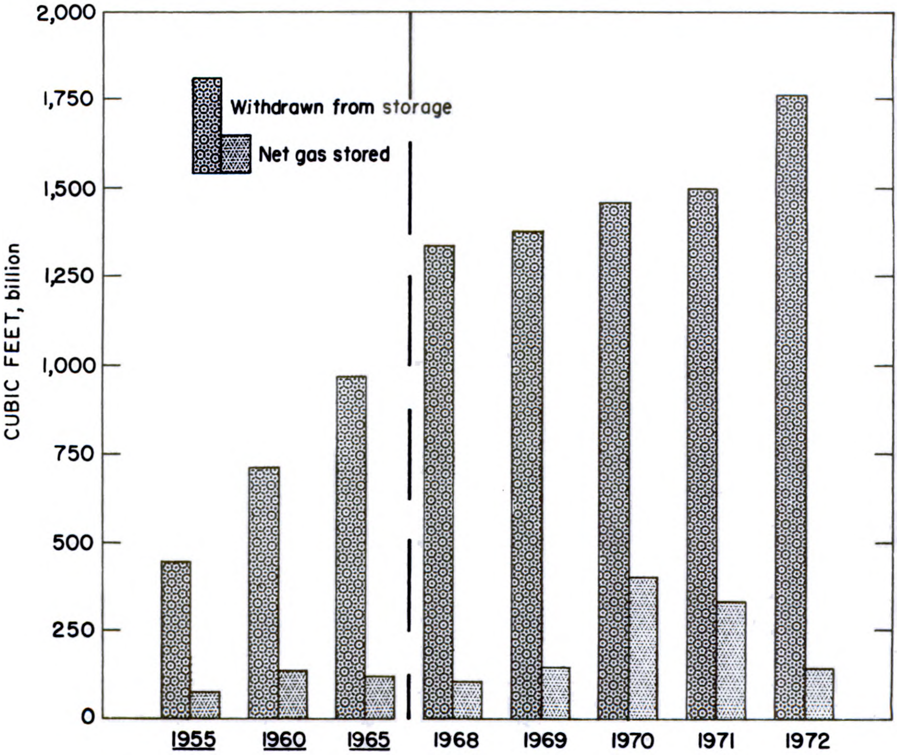


Figure 3.—Trends in net gas stored underground in U.S. storage fields.

There were, as of June 30, 1972, 22 LNG facilities for peak shaving purposes in operation and these had storage capacity aggregating 25,947 MMcf. Also, the 22 plants had a liquefaction capacity of 206 MMcf per day, In addition there were 17 plants, either proposed or pending operation, with storage capacity of 18,900 MMcf and a gross liquefaction capacity estimated at 95 MMcf per day.

For peak shaving purposes, relatively small quantities of gas are stored for use during the high-consuming, low-temperature winter months. Furthermore, because the regasification rate is rapid during these months, when the occasion demands it, LNG storage could be depleted in less than 1 week.

During 1972, the total amount of gas moved into storage aggregated 1,892,952 MMcf, as shown in table 16. Over the same period, 1,757,218 MMcf was drawn down, leaving a net stored of 135,734 MMcf by the end of 1972.

Where depleted fields, whether oil or gas, are not available, other types of underground storage come into use. For example, there are 46 acquifers in nine States in which natural gas is stored. Illinois is the leader with 19; Indiana ranks second with 11 acquifers. Acquifer storage accounts for 21% of the storage total and 16.7% of the maximum daily withdrawal.

The development of storage reservoirs has been a factor in the growth of natural gas demand, particularly in the residential househeating market in which there is a high degree of seasonal variation. Furthermore, the concentration of storage relatively close to the largest markets for residential heating is another very large plus value. Pennsylvania, for example, had 574.1 billion cubic feet of natural gas stored in 68 dry-gas reservoirs at the end of 1972. In Illinois, there were 508.3 billion cubic feet; Michigan was third with 376.6 billion cubic feet of stored gas. Both Ohio and West Virginia had about 350 billion cubic feet of gas stored. In the aggregate, these five States accounted for 2,159.8 billion cubic feet or 61.3% of the total gas in storage, as shown in table 15.

VALUE AND PRICE

Marketed production of natural gas again increased in value in 1972. Values aggregated $4,185,869,000 as compared with a revised total of $4,085,482,000 in 1971 or an increase of 2.5%. These values are based on marketed production of 22,531,698,000 Mcf in 1972 with an average value of 18.6 cents per Mcf. In 1971, marketed production totaled 22,493,012,000 Mcf with an average value of 18.2 cents per Mcf as indicated in table 17. Two States, Texas and Louisiana, accounted for 72.8% of the total marketed production valued at $4,185,869,000 and when Oklahoma and New Mexico are included, the four States account for 87.2% of production and 85.2% of value.

Part of the increase in marketed production was offset by the decline, in Louisiana, of 109 billion cubic feet in volume and a $6 million drop in value. Texas in contrast, reported 107 MMcf or a 1.3% gain in marketed production and a $43 million or a 3% increase in value. At the other end of the spectrum are those States close to markets or doing a sizable intrastate volume relative to total marketed production. In the intrastate category is Alabama. With startups of natural gas processing plants, of which sulfur recovery facilities are an intregal part, production increased tenfold and values jumped from 15.1 cents per Mcf in 1971 to 35.2 cents per Mcf in 1972. Likewise, in Mississippi, and expansion in intrastate sales, which are not under FPC regulations, is reflected in the year-to-year increase from 20.9 cents per Mcf in 1971 to 27.0 cents per Mcf in 1972. In those States relatively close to large markets, such as New York, Pennsylvania, and West Virginia, values increased as evidenced in table 17.

In California, however, although gas-well production increased 10.7 million Mcf, there has been a 20.5% drop in marketed natural gas resulting from a decrease of 34,647,000 Mcf in the production of gas from oil wells. Overall values dropped about $20.4 million. The precipitous drop in California's natural gas production is occurring at a time when oil production is holding at a high level. Part of this decline is attributable to the use of gas in secondary recovery projects, primarily in the Coles Leves North, and Coles Leves

South fields in the Bakersfield area of California.

Wholesale Prices.—The increase in wholesale prices for gas also has been significant, particularly in those markets which have substantial use of gas for residential heating. The FPC collects data on the average wholesale prices in large metropolitan areas. In 12 of the 14 areas surveyed by the FPC, residential heating provides a significant market for natural gas. A 5-year historical series of average wholesale natural gas prices in the 14 large metropolitan areas, in cents per Mcf, is shown in table 18.

Comparing July 1, 1972 prices with those prevailing on July 1, 1971, wholesale rates in 5 of the 14 cities increased by 1 cent to 4 cents or more per Mcf. From July 1, 1971, to July 1, 1972, rates increased nominally or were unchanged in three cities; rates increased by 5 cents or more in four other cities. In two other cities, Washington and Pittsburgh, Pa., there were decreases of 1.35 cents and 0.52 cents per Mcf, respectively.

The wholesale prices for gas for those cities cited, are based on the effective FPC gas tariffs. In cities served by more than one pipeline, prices are based on weighted average charges. Prices reflect deliveries at the city gate except for Los Angeles and San Francisco, where distributors must transport gas from the California-Oregon and California-Arizona State lines.

Retail Prices.—At the retail level, the Bureau of Labor Statistics (BLS) compiles price information for fuels and energy, relative to development of the BLS Consumer Price Index. Average prices for fuels and energy are published monthly for the 20 Standard Metropolitan Statistical Areas shown in table 19.

At retail, gas is sold by gas utilities either in therms or in Mcf units. A therm contains 100,000 Btu. For illustrative purposes, 1 cubic foot of natural gas contains about 1,000 Btu, so that 1 therm would be equivalent to about 100 cubic feet of natural gas and 100 therms to about 10 Mcf. Since both the average wellhead value and the FPC wholesale price series are on million-cubic-foot basis, the BLS retail price series shown in table 19 has been converted from 100 therms to 10 therms so that the retail price approximates the cost of 1 Mcf.

Although retail prices of natural gas have been moving upward for some time now, significant increases are a recent development as indicated in table 19. For example, the price of gas at retail was 1.447 for 10 therms in Boston in 1965. By the end of 1970 that price was 1.568 cents or 8.4% higher than in 1965. Between the end of 1970, and the end of 1972, however, the retail price of gas in Boston jumped from 1.568 cents to 1.814 cents or 15.7%, and New York prices from 1.363 to 1.660 or 21.8%. Further increases are a foregone conclusion in light of actions taken by the FPC in Opinions and Orders related to pricing.

In examining these retail prices it should be recognized that the 100-therm price is a "block price" for gas used for heating. The rate structure of utilities is broken into block meter rates. The first block contains a minimum charge. In 1973 monthly bills for 10 therms for uses other than heating ranged from $1.65 in Dallas to $5.56 in Boston. Most bills (23 cities) cluster between $2.50 and $4 monthly. Minimum charges are a standard characteristic of gas distributors' rate schedules. In those areas where gas for househeating is a major consideration in terms of gas used, the block meter rate, after the block containing the minimum charge, would be lower per therm. The prices shown in table 19 are not true "bill" prices, but "heating block (s) " prices.

FOREIGN TRADE

Exports of natural gas aggregated 78 billion cubic feet in 1972 and 61% of the total volume was shipped in liquid form from Port Nikiski, Alaska.

Exports of LNG continued at high levels in 1972. Exports to Japan aggregated 47,881,678 Mcf, valued at $26,694,585, as compared with 50,230,855 Mcf valued at $26,189,991 in 1971.

Exports via pipeline in 1972 were almost equally divided between Canada and Mexico. Pipeline exports to Canada nearly all of which exit at Detroit, increased 8.2% to 15,426,455 Mcf in 1972.

Likewise, exports of natural gas via pipelines to Mexico, have been trending upwards since 1965; from 9.5 billion cubic feet that year to nearly 15.8 billion cubic feet in 1971. There was a 7.6% decrease in exports to Mexico in 1972, primarily because of reduced sales to intrastate companies. Comparisons of exports in 1971 and 1972 are shown in table 20.

Imports of natural gas from Canada crossed the 1 trillion cubic feet mark in 1972. Imports from Canada aggregated 1,009,092,757 Mcf, an increase of 10.8%. The price of Canadian imported gas in 1972 increased about 10.6% over the 27.82 cents per Mcf in 1971. Imports from Canada in 1972 were valued at $310.5 million, a 22.5% increase over the 1971 total of $253.4 million in 1971. On a daily average basis, Canadian imports by pipelines averaged nearly 2,757 MMcf as compared with almost 2,496 MMcf per day in 1971.

Although imports from Canada have been growing, imports from Mexico have been moving in the opposite direction. In fact, imports from Mexico entering the United States at McAllen, Texas, were 60.7% lower in 1972, primarily because supplies available for export to the United States are diminishing rapidly. For example, in 1971, imports from Mexico were 20.7 billion cubic feet compared with 41.3 billion cubic feet in 1970. In 1972, imports from Mexico were cut again—this time to 8.1 billion cubic feet or an 80% reduction over the 2-year period. A comparison of 1972 developments with 1971 is shown in table 21.

In addition to pipeline imports, 674,028 barrels of LNG were imported. At 14.73 psia, these volumes are equivalent to 2,261,508 Mcf of natural gas. Nearly 90% of the LNG was received from Algeria; the remainder originated in Canada. These LNG imports are primarily for peak shaving. Relative to base-load gas, the El Paso Natural Gas Co. finalized negotiations in 1972 with the Algerian government to import 1 billion cubic feet of natural gas per day as LNG or a total of 9 trillion cubic feet over the 20-year contract period. This plan has been approved by the FPC. The gas is to be landed at Cove Point. Md., and at Elba Island near Savannah, Ga. Facilities to receive and store base-load LNG are to be built; also regasification plants and pipeline connections to move gas to markets will be essential adjuncts to these projects. However, base-load Algeria LNG imports are not expected before 1976.

WORLD REVIEW

Marketed production of natural gas, worldwide, climbed to a record high in 1972. World production aggregated 42,481,435 MMcf, according to preliminary estimates and, of this total, the United States accounted for 22,531,698 MMcf, or 53.0%. In 1968, the United States accounted for 61.7% of the world total marketed production.

The U.S.S.R. was second to the United States, accounting for 18.5% of world production. During 1972, marketed production in the U.S.S.R. was estimated to have been 7.8 trillion cubic feet, an increase over 1971 of 300 billion cubic feet. The trend upward continued as the U.S.S.R. established new markets, primarily in Western Europe. The completion of a natural gas pipeline across Czechoslovakia paved the way to move Soviet natural gas to Italy and West Germany, The new line connects the Soviet Union and Austria.

A consortium of German steel manufacturers have contracted to deliver 1,200,000 tons of large diameter pipe to the Soviet Union. Repayment will be made in large-scale deliveries of natural gas to West Germany. Total deliveries to West Germany, Italy, Austria, Finland, and France are expected to reach 700 billion cubic feet by the late 1970's.

The cooperation of American oil, gas, and engineering companies to assist in the development of Soviet resources has received impetus from the policy formulated between the United States and the U.S.S.R. in May 1972.

In July 1972, the Occidental Petroleum Corp. signed a 5-year scientific and technical agreement with the State Committee for Science and Technology of the Council of Ministers of the U.S.S.R. This agreement covers exploration, production, and usage of oil and gas; agricultural fertilizers and chemicals; metal treating and metal plating; as well as the utilization of solid wastes. As a result of this agreement, there is a strong likelihood that natural gas will be available from Siberia for export as LNG to the United States, both to east coast and west coast.

Japan proposes, also, to participate in this development work so that some of the Soviet natural gas may become available for Japanese needs. It is estimated that proven reserves of natural gas in the U.S.S.R. are about 18 trillion cubic meters or about 636 trillion cubic feet.

Other American companies, such as El Paso Natural Gas, Bechtel International, Texas Eastern Transmission, Tenneco Corp., and Brown & Root, Inc., have been negotiating with the Soviet Union relative to development of its oil and gas supply potential.

Natural gas production in Canada was 2,913,645 MMcf in 1972 compared with 2,499,024 MMcf in 1971, an increase of 414.6 billion cubic feet or 16.6%.

Canada ranks third in natural gas production, exceeded only by the United States and the Soviet Union. About 40% of the total natural gas produced in Canada is exported to the United States, a fact that has caused concern about the availability of energy for needs in Canada. As a result, the National Energy Board has placed restrictions on exports of liquid hydrocarbons and natural gas. Similar to the case in the United States, air pollution controls and fuel use restrictions are swelling the demand for gas in Canada. This action was motivated, in part at least, by a report, completed in December 1972,[8] which was decidedly pessimistic about the long-term supply of conventional oil and gas resources.

Meanwhile, exploration and new oil and gas discoveries in the "frontier" regions, the Mackenzie Delta and Arctic Islands in the far north, and along the Atlantic offshore shelf in the east were encouraging. In fact, major reserves of natural gas have already been established in the Delta and in the Arctic Islands by Canadian and American oil and gas transmission companies and groups. Also a joint Canadian Government and industry venture, which is exploring and drilling in the Arctic Islands from the Benfort Sea to Baffin Bay, has blocked out large reserves of natural gas. It is estimated that natural gas reserves blocked out so far are at the 15-trillion-cubic-foot mark. In addition, exploration has intensified along Canada's east coast. The Department of Energy, Mines, and Resources has issued permits on 300 million acres in the Atlantic and Gulf of St. Lawrence. Discoveries in the Scotian shelf area around Sable Island have been most promising; capital from U.S. companies is playing an important role in the search and development of the Canadian oil and natural gas potential.

Marketed production from the Netherlands in 1972 totaled 2,052,443 MMcf. This volume is 515,944 MMcf, or 33.6% greater than in 1971 and 1,565,350 MMcf or more than 4 times greater than in 1968. Likewise, gas sales continued to boom in the Netherlands and it is estimated that natural gas sales totaled 58,000 million cubic meters or 2,048,270 MMcf in 1972.

Natural gas from the Netherlands has become a premium fuel for Western Europe so that there has been a significant drain on the country's gas reserves. As a result, the Netherlands Government placed a ban on new gas export contracts with West Germany until substantial new natural gas reserves are found.

Meanwhile, the Netherlands Government has granted 16 companies or groups of companies exploration licenses to drill for oil and gas offshore in the Netherlands. A number of these blocks of offshore acreage are shaping up as promising gasfields, and exploration is just beginning to gather momentum.

Romania ranks fifth in natural gas production. It is estimated that production in 1972 was about 954,000 MMcf or about 2% higher than the 943,568 MMcf produced in 1971. Most of the gas produced is used internally. Industry use, for fuel and petrochemical feedstocks, is an important consumer of gas in Romania.

The North Sea remains one of the most promising natural gas areas of the world outside the Soviet Union and the Middle East. Estimates by the United Kingdom, Norway, and the Netherlands of gas reserves range widely, from about 70 to 140 trillion cubic feet. In addition, there are production areas offshore of Denmark, France, and West Germany. In the 7-month period, January-July 1972, the total production of British North Sea gas averaged 2,507.5 MMcf per day or a 47.9% increase over the 1,695.8 MMcf per day in the comparable 1971 period. Further increases are expected as a result of new discoveries north and east of Scotland and the gas discovery northwest of the Frigg gasfield which brackets the United Kingdom-Norway median line.

---

[8] An Energy Policy for Canada Phase I. V. 1, Analysis; v. 2 Appendices; Summary of Analysis Department of Energy, Mines and Resources, Ottawa. Available, Information Canada, Ottawa—price $10.00.

Algeria's marketed production is becoming a very important factor to the United States in view of long-range plans to import natural gas as LNG. The El Paso Natural Gas Co. contracted initially with Société Nationale pour la Recherche, la Production, le Transport, la Transformation et la Commercialisation des Hydrocarbures (SONATRACH) to import LNG averaging 1 billion cubic feet per day of gas rated at 1,125 Btu's per cubic foot. This was the first base-load contract to import LNG on a large scale.

Subsequently, a contract was made to purchase another 1 billion cubic feet per day, lifting the total to an average of 2 billion cubic feet a day over a 25-year period. However, the FPC has yet to approve the second 1 billion-cubic-feet-per day contract between SONATRACH and El Paso. In addition, a contract has been made with Distrigas Corp., of Boston to provide 50 MMcf per day over a 20-year period. Also, Eascogas LNG, Inc., agreed to buy 120 billion cubic meters (4,238 Mcf) over a 22-year period. This was a relatively recent transaction. In addition, SONATRACH has been negotiating with companies from West Germany, Belgium, France, and Spain to supply Europe with LNG over the longer term.

TECHNOLOGY

The predicted scarcity in natural gas supplies over the longer term has stimulated action on the part of industry and Government to spearhead research in the development of the gasification of coal, to obtain a high-Btu gas which is virtually the same in characteristics as pipeline-quality natural gas.

Construction of a $12-million facility at Bruceton, Pa., to demonstrate the Bureau of Mines coal gasification process is expected to be finished in August 1974. When completed, the pilot plant will be capable of processing about 75 tons of raw coal per day into substitute natural gas. The gasifier is designed to operate at 1,000 pounds per square inch and 1,800° F, and to produce 100,000 standard cubic feet per hour (SCFH) of coal gas. One fourth of the raw gas will be further processed to produce 13,000 SCFH of pipeline-quality gas. The pilot plant will be operated on a variety of U.S. coals to provide definitive process information on which to design a commercial coal-to-synethic natural gas (SNG) plant. A commercial plant would have a capacity of 250 MMcf of pipeline-quality gas per day.

Liquid gasification, that is synthesis of pipeline quality gas from petroleum hydrocarbons, has been attained in two liquid gasification plants. In fact, two plants, one in Harrison, N.J., and the other in Marysville, Mich., have been tested and found operable. There are within the United States, 31 plants for which plans have been announced to build gasification facilities. A summary of proposed LSNG plant construction is as follows:

Feedstock	Number of plants	Feedstock (barrels per day)	LSNG production (million cubic feet per day)
Naphtha	[1] 19	749,200	2,873
Natural gas liquids	4		
Propane/butane	3	17,860	70
Crude oil	[1] 5	780,000	[2] 1,680
Total	31	1,547,060	4,623

[1] Feedstock requirements and LSNG production of one naphtha plant and two crude oil plants not available. Only 18 naphtha plants are identifiable.

[2] Plus low-sulfur fuel oil production of 341,000 to 446,000 barrels per day.

As shown in the tabulation, more than half of the plants are designed to operate on naphtha as a feedstock and most of these proposed plants are to be located along the eastern seaboard in order to be accessible to naptha imported from Western Europe and the Caribbean areas. The LSNG plant in Harrison, N.J., is using domestic naphtha as a feedstock. The other LSNG plant in Marysville, Mich., is using natural gas liquids, part of which is obtained from Canadian sources and partly from U.S. sources.

Nuclear stimulation is another procedure for augmenting the supply of natural gas. The Atomic Energy Commission has conducted three experiments to determine the feasibility of using nuclear stimulation in the recovery of natural gas in tight formations. The first, the 1967 Gas Buggy experiment in New Mexico was a 29-kiloton shot. Subsequently, a 43-kiloton shot was made at Rulison in Colorado in 1969. Both of these shots proved that the flow of gas could be stimulated, but there was some tritium contamination.

The third experiment, also in Colorado, was the Project Rio Blanco Phase I which consisted of the near simultaneous detonation of three 30-kiloton nuclear explosives spaced one above the other more than 1 mile underground. The detonation has taken place but reentry into the well will not occur until September 1973.

Table 2.—Gas industry failures reported during 1971–72[1]

Cause	Total number of failures		Fatalities				Injuries				Estimated property damage (value)	
			Employees		Non-employees		Employees		Non-employees			
	1971	1972	1971	1972	1971	1972	1971	1972	1971	1972	1971	1972
Distribution:												
Corrosion	120	121	--	--	3	2	9	9	30	56	$297,474/$574,146	
Damage by outside forces	575	630	--	--	13	20	8	15	138	141		
Construction defect or material failure	121	90	--	1	16	3	4	3	111	52

Transmission:												
Corrosion	55	74	1	--	--	--	6	--	--	--	2,632,170/2,424,747	
Damage by outside forces	213	219	--	--	1	--	--	8	6	4		
Construction defect or material failure	105	80	--	--	--	2	--	4	3	1		
Other causes	37	36	1	3	--	1	8	11	1	8		
Total	410	409	2	3	1	3	14	23	10	13	2,632,170	2,424,747
Grand total	1,287	1,293	8	5	37	29	51	55	340	275	2,929,644	2,998,893

[1] In addition to above data compiled from written gas pipeline failure reports received by the Office of Pipe line Safety (OPS) during 1972, there were two fatalities and 39 injuries resulting from gas distribution incidents and one injury resulting from a transmission line failure, all of which occurred in 1972 but were not reported until after December 31. Also, additional incidents reported to OPS by telephonic notice during 1972, but which did not require follow-up written reports, indicated that there were 18 fatalities and 64 injuries from distribution system failures.

XX Not applicable.

[1] Firm requirements as reported in Gas Supply-Requirement Balance. Volume curtailed as reported in FPC Form 17.

[2] All volumes reported in Gas Supply-Requirement Balance.

[3] Cities Service did not file Form 17 reports. The volumes shown were reported in Gas Supply-Requirement Balance. The company states "our entire contractual demands for gas on our system although some volumes of gas sold and delivered to distributors for resale and to direct customers are interruptible."

[4] Intercompany transactions as obtained from FPC Form 17.

[5] Estimated intercompany transactions.

Source: Federal Power Commission.

---

[1] The net difference between gas stored in and gas withdrawn from underground storage reservoirs, inclusive of adjustments and native gas transferred from other reserve categories.

[2] Preliminary net production.

[3] Gas held in underground reservoirs (including native and net injected gas) for storage purposes.

[4] Includes offshore reserves.

[5] Includes Arizona, Iowa, Maryland, Minnesota, Missouri, South Dakota, Tennessee, Washington.

e Estimate. p Preliminary. r Revised.

[1] In addition to the countries listed, Albania, Cuba, Mongolia, and Thailand produce crude oil and presumably produced natural gas, but available information is inadequate to estimate output levels and the share of gross production that is a classifiable as marketed.

[2] Comprises all marketed production (see footnote 3) plus gas vented, flared, reinjected for repressuring and used to drive tubrines (without being burned).

[3] Comprises all gas collected and utilized as fuel or as a chemical industry raw material, including gas used in oil and/or gasfields as a fuel by producers, even though it is not actually sold.

[4] Apparently, natural gas that is vented or flared is not included in reported gross production; marketed output presented here is the difference between reported gross production and reported injected into reservoirs.

[5] Total production is obtained from coal mines.

[6] Gross production not reported; marketed output has been reported in lieu of a gross production estimate because the quantity flared, vented and/or reinjected is believed to be small.

[7] Includes output from coal mines as follows in million cubic feet: Czechoslovakia: 1970—11,442; 1971—12,290;1972—13,000 (estimate); West Germany; 1970—19,670; 1971—20,165; 1972—20,482 (estimate); Poland: 1970—7,310; 1971—7,734; 1972—7,950 (estimate); United Kingdom: 1970—5,686; 1971—4,838; 1972—4,600 (estimate).

[8] No marketed production reported; there probably is some small field use, but available information is inadequate to make reliable estimates.

[9] Revised to include output from coal mines, not previously included.

[10] Available statistics used for both gross and marketed production comprise marketed production plus gas used for repressuring, but exclude gas vented and/or flared. In 1968 (latest available figure), gas used for repressuring constituted only 0.4% of the total. Information is inadequate to make a reliable estimate of gas vented and/or flared, but it is believed to be small.

[11] Marketed production not reported; gross production (officially reported) has been used in lieu of a marketed production estimate because the quantity flared, vented and/or reinjected is believed to be small (less than 10%).

[12] Data are for year beginning March 21 of that stated.

[13] Data are for year ending June 30 of that stated.

[14] Includes ½ of production reported for the former Kuwait-Saudi Arabia Neutral Zone.

Natural Gas Liquids

By S. O. Wood, Jr.[1] and Leonard L. Fanelli[2]

Production of natural gas liquids from gas-processing plants increased to an alltime high of 638.2 million barrels. This production was 20.4 million barrels more than the 1971 output, an increase of 3.3%. Natural gas liquids production was valued at $1,452 million, 4.8% higher than the 1971 value of $1,386 million.

Natural gas liquids are products obtained from the processing of natural gas at natural gasoline plants, cycling plants, and fractionators. Included are ethane, the liquefied petroleum gases (LPG—butane, propane, and butane-propane mixtures), isobutane, mixed gases, natural gasoline, plant condensate, and finished products including gasoline, special naphthas, jet fuel, kerosine, distillate fuel oil, and miscellaneous finished products.

Continued demand for petrochemical feedstock and increased recovery capability contributed to the 20-million-barrel, 25%, increase in ethane production. Propane production increased 2.8% to 218.0 million barrels. Total butanes output increased 1.4% to 122.5 million barrels. Natural gasoline production was 156.5 million barrels, 2.1% less than in 1971. Isopentane output increased 30.3% to 7.2 million barrels. Plant condensate production decreased 14.5% to 22.0 million barrels.

Record high production contributed to an alltime natural gas liquids stock inventory of 108.9 million barrels at plants, including underground storage, in September 1972. The LPG portion of the stock inventory was 97.6 million barrels, compared with 92.0 million barrels in September 1971.

Earlier than usual cold weather, an unusually wet corn crop, and curtailment of natural gas deliveries precipitated a propane supply imbalance in some Midwestern States late in the year. By yearend propane futures for December 1973 delivery were 8 cents per gallon, about 40% higher than 4 months earlier.

The average unit value of natural gas liquids production was $2.28 per barrel, an increase of 1.8% from the comparable 1971 value. Unit values increased for all natural gas liquids components except the "Other products" category. LPG and ethane value increased 3.8% to $1.91 per barrel. Natural gasoline and isopentane value was $3.06 per barrel, an increase of 2.0% over the 1971 average. Plant condensate value increased 0.6% to $3.39 per barrel. Finished gasoline and naphtha unit value increased 7.4% to $4.66 per barrel. Other products average value declined 1.5% to $2.58 per barrel.

Data presented in this chapter were compiled from operating reports of natural gasoline plants, cycling plants, and fractionators that process natural gas. Included are all natural gas liquids except the small volume, considered to be insignificant in the national and State totals, recovered at pipeline compressor stations and gas dehydration plants. Plant condensate is included in natural gas liquids; field-separated condensate, however, is included with crude oil. Ethane and liquefied gases such as butane and propane, recovered from the crude oil refining operations, are classed as liquefied refinery gases (LRG) and reported as refinery products.

Annual reports were received from all large producers and distributors and from most of the dealers that sell more than 100,000 gallons of LPG per year. To reflect total shipments, the sample of dealer shipments was expanded by Petroleum Administration for Defense (PAD) districts on the basis of domestic demand in the districts.

Components of natural gas liquids used in this chapter are defined as follows:

Butane.—Includes all products covered by NGPA specifications for commercial butane, except those that contain 80% or more isobutane.

---

[1] Petroleum engineer, Division of Fossil Fuels.

[2] Survey statistician, Division of Fossil Fuels.

Butane-Propane Mix.—Includes all products covered by NGPA specifications for commercial butane-propane mixtures.

Distillate Fuel Oil.—Includes all light oil for shipment as fuel, including diesel fuel oil.

Ethane.—Includes ethane only. All other LPG mixed with ethane are reported in their respective product classification.

Gasoline.—Includes all products within the gasoline range for shipments as motor fuel.

Isobutane.—Includes all products covered by NGPA specifications for commercial butane, which contains 80% or more isobutane.

Isopentane.—Includes segregated isopentane.

Jet Fuel.—Includes all aviation turbine engine fuel for both military (JP-4 and JP-5) and commercial use.

Kerosine.—Includes all grades of kerosine or range oil.

Natural Gasoline.—A hydrocarbon mixture used primarily for blending or further processing into finished gasoline.

Other Products.—All products not otherwise classified.

Plant Condensate.—Includes those liquids, mostly pentanes and heavier, recovered and separated at raw natural gas inlet separators and scrubbers.

Propane.—Includes all products covered by the Natural Gas Processors Association (NGPA) specifications for commercial and HD-5 propane.

Special Naphtha.—Includes all hexanes and heptanes.

Production of natural gas liquids is reported by States; however, production for Louisiana and Texas is also reported by districts. Louisiana is divided into an Inland district and a Gulf Coast district. The Gulf Coast district includes Vernon, Rapides, Avoyelles, Pointe Coupee, West Feliciana, East Feliciana, Tangipahoa, St. Helena, and Washington Parishes and all parishes in the State south of these. All parishes not included in the Gulf Coast district are in the Inland district.

The Bureau of Mines producing districts in Texas correspond, with one exception, to groupings of Texas Railroad Commission districts:

Bureau of Mines districts	Railroad Commission districts
Gulf Coast	Nos. 2 and 3.
West Texas	Nos. 7C, 8 and 8A.
East Proper	Part of No. 6 (East Texas field in Cherokee, Smith, Upshur, Rusk, and Gregg Counties).
Panhandle	No. 10.
Rest of State:	
North	Nos. 7B and 9.
Central	No. 1
South	No. 4
Other East Texas	Nos. 5 and 6 (exclusive of East Proper).

The Bureau of Mines also groups refineries by geographical refining districts. These refining districts may be combined to correspond with the PAD districts, as follows:

PAD I.—*East Coast.*—District of Columbia, Maine, New Hampshire, Vermont, Massachusetts, Rhode Island, Connecticut, New Jersey, Delaware, Maryland, Virginia, North Carolina, South Carolina, Georgia, Florida, the following counties of New York: Cayuga, Tompkins, Chemung, and all counties east and north thereof, and the following counties of Pennsylvania: Bradford, Sullivan, Columbia, Montour, Northumberland, Dauphin, York, and all counties east thereof.

PAD I.—*Appalachian No. 1*—West Virginia and those parts of Pennsylvania and New York not included in the East Coast district.

PAD II.—*Appalachian No. 2*—The following counties of Ohio: Erie, Huron, Crawford, Marion, Delaware, Franklin, Pickaway, Ross, Pike, Scioto, and all counties east thereof.

PAD II.—*Indiana-Illinois-Kentucky*—Indiana, Illinois, Kentucky, Tennessee, Michigan, and that part of Ohio not included in the Appalachian district.

PAD II.—*Oklahoma-Kansas, Missouri*—Oklahoma, Kansas, Missouri, Nebraska, and Iowa.

PAD II.—*Minnesota-Wisconsin-North Dakota-South Dakota*—Minnesota, Wisconsin, North Dakota, and South Dakota.

PAD III.—*Texas Inland*—Texas, except Texas Gulf Coast district.

PAD III.—*Texas Gulf Coast*—The following counties of Texas: Newton, Orange, Jefferson, Jasper, Tyler, Hardin, Liberty, Chambers, Polk, San Jacinto, Montgomery, Galveston, Waller, Fort Bend, Brazoria, Wharton, Harris, Matagorda, Jackson, Victoria, Calhoun, Refugio, Aransas, San Patricio, Nueces, Kleberg, Kenedy, Willacy, and Cameron.

PAD III.—*Louisiana Gulf Coast*—The following parishes of Louisiana: Vernon, Rapides, Avoyelles, Pointe Coupee, West Feliciana, East Feliciana, Tangipahoa, St. Helena, Washington, and all parishes south thereof; the following counties of Mississippi: Pearl River, Stone, George Hancock, Harrison, and Jackson; and in Alabama: Mobile and Baldwin Counties.

PAD III.—*North Louisiana-Arkansas*—Arkansas and those parts of Louisiana, Mississippi, and Alabama not included in the Louisiana Gulf Coast District.

PAD III.—*New Mexico*—New Mexico.

PAD IV.—*Rocky Mountains*—Montana, Idaho, Wyoming, Utah, and Colorado.

PAD V.—*West Coast*—Washington, Oregon, California, Nevada, Alaska, Arizona, and Hawaii.

Some data in the chapter are based on the Bureau of Mines refining districts, and others refer to the PAD districts. Maps showing the PAD and Bureau of Mines refining districts appear in the Crude Petroleum and Petroleum Products chapter of this Minerals Yearbook volume.

DOMESTIC PRODUCTION

Domestic production of natural gas liquids totaled 638.2 million barrels, a 3.3% increase over that of 1971. Growth in the volume of ethane extraction was the principal contributor to the 20-million-barrel increase in natural gas liquids output in 1972.

Historic production of natural gas liquids and categories of principal components are shown in figure 1. Figure 2 illustrates the relative production of natural gas liquids principal components in 1972. LPG production increased 2.1% to 344.0 million barrels and accounted for 53.9% of

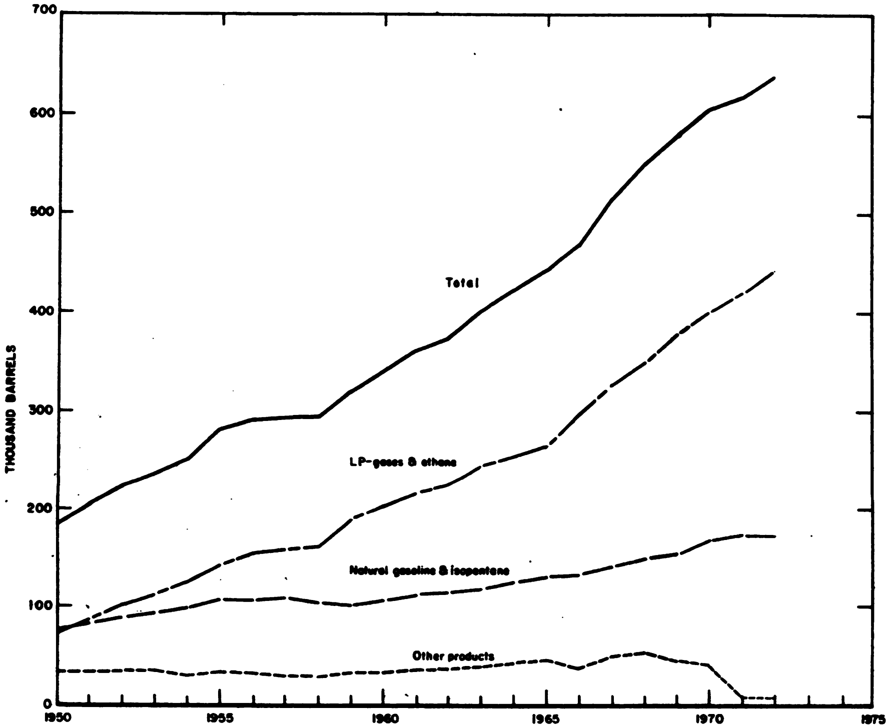

Figure 1.—Production of natural gas liquids in the United States.

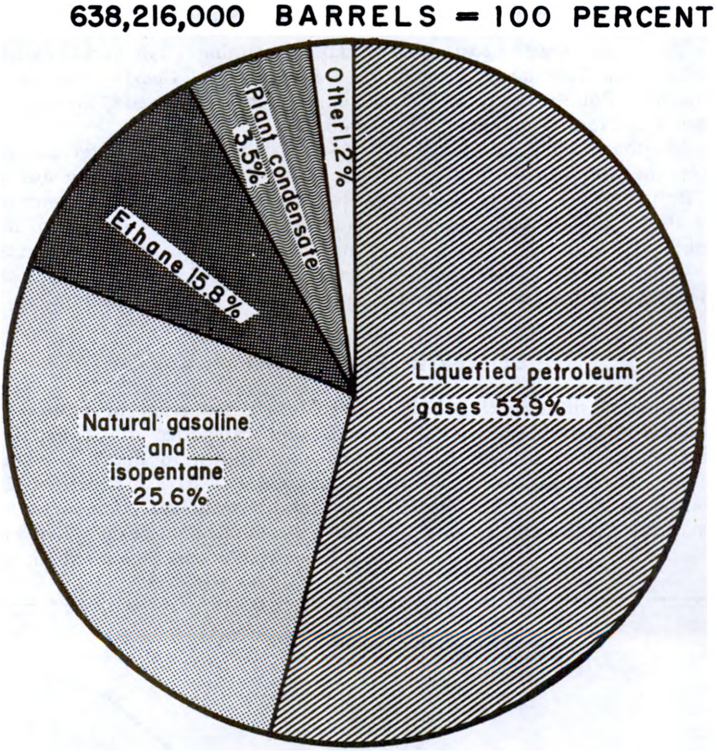

Figure 2.—The relative production of natural gas liquids components, 1972.

natural gas liquids output. Propane production was 218.0 million barrels, 2.8% higher than in 1971. Production of butanes (normal, other, and isobutane) aggregated 122.5 million barrels, 1.4% higher than in 1971. Natural gasoline and isopentane output totaled 163.7 million barrels, 1.0% less than comparable 1971 output. Ethane production of 100.7 million barrels was 15.8% of total natural gas liquids output. Production of plant condensate declined for the fourth consecutive year. Output of 22.0 million barrels was 14.5% less than in 1971.

Production of finished petroleum products at natural-gas-processing plants totaled 7,757,000 barrels. Motor gasoline accounted for 53.9% of the finished products, and other components included kerosine, 13.7%; distillate fuel oil, 15.7%; special naphthas, 3.4%; and miscellaneous products, 13.3%.

RESERVES

The American Gas Association, Inc. (AGA) Reserves Committee estimated that natural gas liquids proved reserves at yearend 1972 totaled 6,787 million barrels, a decline of 7%. This was the fifth consecutive year in which proved reserves have declined. According to AGA data, the yearend reserve to 1972 production ratio was 9.0:1, compared with 13.4:1 in 1967, when proved reserves were at an alltime high. Reserve additions from the discovery of new fields and new reservoirs totaled 87 million barrels. These additions were principally in Louisiana (41.1 million barrels), Texas (27.1 million barrels), and Alabama (9.6 million barrels). Texas accounted for 42.6%, and Louisiana accounted for 31.5% of the Nation's proved natural gas liquids reserves at yearend 1972. Although reserves estimates were higher in five of the 23 States reported, the overall change in reserves was a decrease of 517.7 million barrels.

PRODUCTIVE CAPACITY

According to the AGA, estimated productive capacity at yearend 1972 was 2,867,000 barrels per day, a decline of 155,000 barrels per day during the year. Increases in productive capacity were estimated for Kansas, up 60,000 barrels per day; Oklahoma, 22,000 barrels per day higher; and Michigan, up 1,000 barrels per day. Significant decreases were reported for Texas, Louisiana, and New Mexico. Respectively, decreases were 168,000, 26,000, and 17,000 barrels per day. Leading States and productive capacity in thousand barrels per day at yearend 1972 were Texas, 1,229; Louisiana, 884; Kansas, 228; Oklahoma, 204; and New Mexico, 168.

As natural gas liquids production is a function of natural gas production and processing, productive capacity is dependent upon rates of gas production from crude oil and natural gas reservoirs. The AGA has defined productive capacity of natural gas liquids as the amount of hydrocarbon liquids that would be produced coincident with the estimated productive capacity of natural gas based on unit recoveries at normal producing rates. Such estimated capacities are not limited by lack of capacity of processing plants or other surface facilities, and it is emphasized that adequate facilities would be required to effect the recovery of liquids from the natural gas produced at these rates. It should also be recognized that such facilities cannot be enlarged quickly. Therefore, the estimated natural gas liquid capacities, which relate to increased production of gas from oil and gas wells operating at their productive capacities, are theoretical and may not be realized in event of an emergency.[3] Although productive capacity estimates determined in accordance with the above definition are theoretical, they are useful in determining potential availability.

The long-term trend of annual increases in capacity of gas-processing plants ended. At yearend, daily capacity was 73.26 billion cubic feet, compared with 75.14 billion cubic feet at yearend 1971, according to The Oil and Gas Journal annual survey.[4] At yearend 1972 there were 786 gas-processing plants, 19 less than at the beginning of the year.

Increases in plant capacity were reported for Colorado, Kansas, Mississippi, Utah, and West Virginia. However, declines in other States resulted in a net decrease of 1.88 billion cubic feet per day in gas-processing capacity.

Texas and Louisiana continued as the leaders in number of plants and processing capacity. Combined, they had 501 plants, 64% of the U.S. total. Capacity of these plants was 52.30 billion cubic feet per day, 71% of the Nation's total.

CONSUMPTION AND USES

Input of natural gas plant products into refineries totaled 302.4 million barrels, an increase of 6.1% from the 1971 level. The increase resulted principally from a 36.3% larger volume of plant condensate input. Of the 53.2 million barrels of plant condensate input, 31.4 million barrels were imports, virtually all from Canada. LPG input to refineries increased from 79.7 million barrels in 1971 to 85.2 million barrels, a 6.9% change. Natural gasoline input to refineries decreased 2.4% to 156.9 million barrels. As indicated below, 51.9% of natural gas plant products input into refineries was natural gasoline. The following is a tabulation of natural gas plant product inputs into refineries in 1,000 barrels:

---

[3] American Gas Association, American Petroleum Institute, and Canadian Petroleum Association. Reserves of Crude Oil, Natural Gas Liquids, and Natural Gas in the United States and Canada and United States Productive Capacity as of Dec. 31, 1971. V. 26, May 1972, p. 108.

[4] Cantrell, Aileen. 1973 Survey of Gas-Processing Plants. Oil and Gas J., v. 71, No. 28, July 9, 1973, p. 98.

	1971	1972	% change
Condensate	39,020	53,190	+36.3
Isopentane	5,541	7,183	+29.6
LPG	79,695	85,198	+6.9
Natural gasoline	160,681	156,879	−2.4
Total	284,937	302,445	+6.1

Domestic demand for liquefied refinery gases (LRG) and LPG totaled 413.6 million barrels, 12.1% higher than the 1971 level. Of the 1972 domestic demand, 292.9 million barrels was for LPG produced at gas-processing plants, 84.0 million barrels was for LRG for fuel use, and 36.7 million barrels was for LRG for chemical use. Propane (including propylene) demand accounted for 326.8 million barrels, or 62.9%. Plant propane demand was 232.6 million barrels. Refinery propane and propylene demand was 94.2 million barrels of which 69.1 million barrels was for fuel use, and the remaining 25.1 million barrels was for chemical use.

Domestic demand for butane (including butylene) increased to 77.3 million barrels. Plant butane demand was 59.4 million barrels. Refinery butane and butylene demand totaled 17.9 million barrels, 12.2 million barrels for fuel use and 5.7 million barrels for chemical use.

Ethane (including ethylene) domestic demand increased significantly, 21.0%, to 106.2 million barrels. Virtually all ethane was used for petrochemical feedstocks. According to the U.S. Tariff Commission, preliminary production of ethylene, the principal market for ethane, increased 2 billion pounds to an alltime high of 20.5 billion pounds. For comparative purposes ethylene production was 5.9 billion pounds in 1960, and 18.5 billion pounds in both 1970 and 1971.

STOCKS

A record high stock inventory of 116.2 million barrels of natural gas liquids was attained September 30, 1972. Stocks at natural-gas-processing plants and terminals (including underground) were 108.9 million barrels, an increase of 9.6 million barrels over comparable stocks on September 30, 1971. Principal stock increases were in propane (8.7 million barrels) and ethane (3.8 million barrels). Stocks of normal butane decreased 3.2 million barrels.

At yearend 1972, total natural gas liquids stocks were 84.2 million barrels, 9.8 million barrels less than comparable stocks at yearend 1971. Natural gas liquids stocks at refineries were 5.0 million barrels at yearend 1972, a decrease of 0.6 million barrels from stocks at yearend 1971. Stocks at plants and terminals (including underground) totaled 79.2 million barrels, 9.2 million barrels less than comparable yearend 1971 stocks. By components, the major stock changes were for propane, down 12.5 million barrels; butane, down 4.1 million barrels; and ethane, up 3.7 million barrels.

PRICES AND VALUE

The average unit value of natural gas liquids was $2.28 per barrel, 1.8% higher than the 1971 average. At yearend propane futures prices had increased significantly, but factors such as alltime record high inventories, influence of long-term contracts, and price constraints set forth by the Federal Government contributed to the small increase in average value. Increases in average unit value for LPG and ethane were virtually nationwide, and total value increased 10.2% to $848 million. LPG and ethane total value accounted for 58.4% of natural gas liquids total value.

Unit value increases for natural gasoline and isopentane increased 2.0%; however, the total value of $500 million was less than an 0.8% increase because production declined. Natural gasoline and isopentane value was 34.5% of natural gas liquids total value.

Although plant condensate average unit value increased 2 cents to $3.39 per barrel, production decreased, and total value declined 14% to $75 million. Unit value of finished gasoline and naphtha increased 32 cents to $4.66 per barrel. Total value declined, however, as production declined 17%. Average unit value for other products decreased 1.5% to $2.58 per barrel.

FOREIGN TRADE

Plant condensate and LPG imports totaled 63.8 million barrels, an increase of 63.6% over that of 1971. The increase was attributed to a continuation of Oil Import Administration regulations that allowed natural gas liquids produced in the Western Hemisphere from Western Hemisphere crude and gas to be imported without being subject to quotas and also to the increasing gap between domestic production and demand.

Plant condensate imports increased from 13.3 million to 31.4 million barrels. Canada supplied 99.5% of plant condensate imports, and the remainder was from Venezuela. LPG imports increased from 25.7 million to 32.4 million barrels, a 26% increase. Canada provided 86% of LPG imports, and Venezuela supplied 12%. Leading suppliers of the remaining 2% ranked as follows: Saudi Arabia, Chile, Libya, Malaysia, Oman, Kuwait, and the United Kingdom.

The distribution pattern of natural gas liquids imports in thousand barrels was as follows:

PAD district	LPG	Plant condensate[1]	Total
I	5,336	798	6,134
II	14,441	16,478	30,919
III	787	--	787
IV	5,405	11,162	16,567
V	6,432	2,990	9,422
Total	32,401	31,428	63,829

[1] Includes natural gasoline.

According to Bureau of the Census data, LPG exports totaled 11.5 million barrels, a 22% increase over 1971 exports. Value of these exports totaled $46.6 million, an increase of 59%. Ninety percent of LPG exports were to Mexico, Japan received 7.7%, Canada received 1.0%, and the remaining 1.3% was distributed among more than 20 countries. LPG exports were comprised of butane, 7.2%; propane, 32.6%; and butane-propane mixtures, 60.2%.

WORLD REVIEW

Production data and sufficient information to make reliable estimates were not available for most nations. Among the reported larger worldwide projects that were approved or under construction were the following:

In Algeria the state-owned petroleum company, Société Nationale pour la Recherche, la Production, la Transport, la Transformation, et la Commercialization des Hydrocarbures (SONATRACH), was constructing two butane and propane units at the north and south sectors of the Hassi Messaoud oilfield. Combined capacity of the two units is 950,000 tons per year (11.2 million barrels). LPG output was scheduled to commence in March 1973.

Approval was granted by Argentina to Hydrocarbons Research, Inc., for constructing a 61,500-ton-per-year propane and butane plant in Santa Fe Province.

In Australia, Esso Standard Oil (Australia) Ltd. was constructing a gas treating and processing plant at Longford, Victoria.

One of the most active countries adding to its gas-processing capability was Canada. Included in the construction program were the following. Amoco Canada completed an 188-million-cubic-foot-per-day (MMcfd) plant at Pointed Mountain, Northwest Territories. At yearend the company was completing a 75-MMcfd plant at Ricinus, Alberta. The plant was designed to recover mixed LPG and pentanes plus heavier hydrocarbons by the refrigeration process. Aquitaine of Canada Ltd. completed an 180-MMcfd expansion of its Ram River plant. This expansion added 22,000 gallons per day of pentanes plus heavier hydrocarbons and also 2,000 long tons of sulfur per day capacity. Canadian Superior Oil Ltd. started an 162-MMcfd expansion at its

Harmattan, Alberta, plant. The refrigeration-absorption process is being used.

Iranian Oil Exploration Co. completed a 500-MMcfd gas-processing plant at Karanj, Iran. Expected natural gas liquids recovery is 10,200 barrels per day.

U.S.S.R. awarded a $24 million contract for engineering and supply of five natural gas drying and condensate-handling plants to the French firm ENSA. Construction started on these plants that were designed to treat 1.4 trillion cubic feet of gas per year from the Jamalo-Nenietzki fields. A 242-MMcfd fractionating plant is to be constructed at the Grosnij field by a French consortium headed by GEXA.

Naftagas Naftna Industrija completed an 100-MMcfd natural gas liquids plant at Mokrin, Yugoslavia.

[1] A producer operating in more than one State is counted only once in arriving at U.S. total.
[2] Represents average unit value of sales throughout the year.
[3] Includes kerosine, distillate fuel oil, and miscellaneous products.

Source: Company reports and Bureau of Mines estimates.

Nickel

By Horace T. Reno [1]

Nickel supply came into closer balance with demand in 1972 because some of the lower grade, high-cost mines were shut down and nickel consumption in the United States, Western European countries, and Japan increased rapidly. Nevertheless, a large surplus nickel supply remained in the producers' inventory that built up in 1970 and 1971.

Canadian nickel producers raised the quoted base price for pure nickel by approximately 15% the first of September. Producers in other countries except the United States followed the Canadian lead.

The U.S. nickel industry was little affected by the worldwide imbalance between supply and demand. The domestic price was not changed until late in the year when the price of domestically produced ferronickel was raised approximately 7%. Domestic consumers used 25% more nickel in 1972 than in 1971 and more than doubled their use of ferronickel.

The President approved legislation on July 26, 1972, that authorized disposal of all nickel held in the national stockpile. Stockpile nickel did not reach the open market during the year.

DOMESTIC PRODUCTION

The Hanna Mining Co. at Riddle, Oreg., was the sole producer of primary nickel in the United States. Byproduct nickel salts were produced at copper and other metal refineries. Part of the byproduct nickel originated from scrap.

r Revised.

[1] Includes only nonferrous nickel scrap added to ferrous and high-temperature alloys.

CONSUMPTION AND USES

The domestic nickel industry used more than twice as much nickel in the form of ferronickel in 1972 than it used in 1971. Essentially all of it was used in stainless and alloy steels. The pattern of nickel consumption in 1972 was changed little from that of 1971; 28% of the total consumed was used to make stainless steels, 12% was used in alloy steels, 18% was used in nickel plating, 26% was used to make high-nickel alloys and superalloys, and 3% was used in iron castings. International Nickel Co. of Canada, Ltd. (INCO), which in the past has reported statistics on the end-use consumption pattern, did not do so for 1972 because of the growing markets in Eastern Europe, the U.S.S.R., and Asia, areas for which accurate statistics are unavailable. Nevertheless, INCO reported little alteration in consumption either as to end use or geographical area. End-use market information available to the Bureau of Mines did not indicate any substantial change in the worldwide pattern of nickel usage.

Total	24,708	16,005	26,205

r Revised.

PRICES

The producers' price for electrolytic nickel was increased from $1.33 to $1.53 per pound the first of September. Prices were unchanged for domestically produced nickel in ferronickel until December 14 when the quoted price was raised from $1.28 to $1.38 per pound. The price changes for nickel produced in foreign countries widened the differential between prices quoted for pure nickel and that quoted for nickel in ferronickel and in other forms of nickel especially suited for steelmaking. The top grade of ferronickel produced in New Caledonia was quoted at $1.42 per pound of contained nickel, an increase of 12 cents per pound effective September 25.

FOREIGN TRADE

The gross weight of U.S. exports of nickel, nickel alloys, and nickel catalysts was 34% less in 1972 than that in 1971. Export of nickel scrap increased 14% over that of 1971.

U.S. foreign trade in nickel in 1972 was marked by greatly increased imports of nickel in ferronickel, 76% more than was imported in 1971. Most of the ferronickel imported originated in New Caledonia. Nickel-bearing ore was imported from Colombia, the Philippines, and Canada for use in pilot plant research operations. The total of nickel in all forms imported for consumption in 1972 was 21% more than was imported in 1971. Canada continued as the principal supplier but with 8 percentage points less of the total than in 1971. Imports of nickel from the U.S.S.R. increased more than fourfold compared with that imported in 1971.

WORLD REVIEW

Australia.—Western Australia's nickel boom of the last 4 years was moderated somewhat by the oversupply of nickel around the world; however, nickel production increased 10% compared with that of 1971. Western Mining Corp., Ltd., again increased its reserves, and by the end of the year, the corporation had essentially completed a new flash smelter at Kalgoorlie. The Kalgoorlie smelter has a designed capacity of 25 tons of nickel concentrate per hour. It utilizes the Outokumpu Oy smelting process. Western Mining Corp.'s progress is a good measure of the rapidity with which the nickel industry of Western Australia has developed into a significant worldwide supplier. Just 5 years after first nickel production, Western Mining was the world's fourth largest producer of nickel and opened a sales office in the United States at Pittsburgh, Pa., to market nickel to North American consumers.

Construction of the mining plant and infrastructure for the Greenvale nickeliferous laterite deposits in Queensland was started, and the work proceeded as scheduled.

Poseidon Ltd.'s joint venture with Homestake Mining Co. and Hanna Mining Co. to exploit the Windarra deposit in Western Australia was disbanded, and Poseidon entered an agreement with Western Mining Corp. and Sherritt Gordon Mines Ltd. of Canada for sale of concentrates produced from the Windarra deposit. Reportedly, the Poseidon company will have some support on the project from the Australian Government.

The Agnew nickel prospect, 200 miles northwest of Kalgoorlie, discovered in 1971 by Selcast Exploration Ltd., a subsidiary of Selection Trust Ltd. of London, was proved a significant find. By yearend it was reported that the Agnew deposit contained 33 million tons of ore averaging 2.2% nickel at a cutoff grade of 1%.[2]

The Western Australian Government considered providing support in building infrastructure that serves the developing nickel and other mineral industries of the state. Reportedly, the most likely aid would be help in building a railway to Kalgoorlie continuing west to the Port of Geralton.

---

[2] Northern Miner. Major Nickel Orebody Shaping From Agnew Find in Australia. V. 58, No. 41, Dec. 28, 1972, p. 14.

Botswana.—The way was cleared for development of the Pikwe-Selebi copper-nickel deposits when agreements for financing the project were signed at Gaborone in March.

Canada.—Canadian nickel production in 1972 was 13% less than in 1971 because INCO cut back its mining operations 10% early in the year to adjust output to market conditions. At yearend INCO had 14 mines operating, 11 in Ontario and 3 in Manitoba. INCO's Maclennan mine in the Sudbury district was depleted, and its Shebandoan mining and milling complex in Northern Ontario was brought into production as planned.

Prospecting and exploration of nickel and copper-nickel properties continued at a high level of activity, little influenced by the worldwide imbalance between supply and demand. INCO and Falconbridge Nickel Mines Ltd. were active in exploration in Quebec, Ontario, and Manitoba. INCO did not report developments at specific properties in its annual report for the year. Falconbridge reported that underground drilling at its Onaping mine indicated a new significant sulfide zone and that diamond drilling from a drift on the 1,000-foot level at the Bucko Lake property of Bowden Lake Nickel Mines Ltd. was in nickel mineralization. Falconbridge had a 60% interest in the property.

Great Lakes Nickel Ltd. of Toronto, Ontario, and Boliden AB of Stockholm, Sweden, announced an agreement under which the Swedish company will study the feasibility of producing copper and nickel concentrates from the large low-grade copper-nickel property on which Great Lakes Nickel has indicated 106 million tons of 0.4% copper, 0.2% nickel ore. A feasibility study made for the Ontario Government indicated that a copper smelter-refinery in northern Ontario would not be economically viable unless large copper ore bodies are discovered. The study cited the Great Lakes Nickel Ltd. project as a possibility.

The principal Canadian nickel producers and their 1972 production, sales, or deliveries to customers as given in their annual report to stockholders were as follows:

Company	Type of operation	Thousand pounds
The International Nickel Co. of Canada, Ltd	Delivery	425,080
Falconbridge Nickel Mines Ltd	Delivery	89,665
Sherritt Gordon Mines Ltd	Sales	20,414

Environmental improvement in the Sudbury district was a major element in the operations of both INCO and Falconbridge. INCO commissioned a 1,250-foot chimney and a gas cleaning system and capped the three chimneys that it replaced. Falconbridge shut down its pyrrhotite processing plant until a process is developed to eliminate sulfur dioxide (SO_2) emissions. Both companies recycled processing waters and seeded barren land in the vicinity of their plants.

Falconbridge closed its nickel-iron refinery after 2 years of operation failed to achieve continuous production of specification products. Reports to the Bureau of Mines from U.S. consumers of the Falconbridge nickel-iron indicated that the material that reached the market was a satisfactory source of nickel for use in steelmaking.

Colombia.—Colombian Nickel Co. (CONICOL) and the Industrial Development Institute of Colombia (IFI) were renegotiating portions of their concession agreement to exploit nickel deposits at Cerro Matoso in the Department of Córdoba.

Cuba.—The Government of the Republic of Cuba announced that it had reached agreement with the Government of the U.S.S.R. for credits to finance general repair and reconstruction of the existing nickel plants at Moa Bay and Nicaro and to expand the mining base at both plants. Moreover, it announced that Cuban and Soviet organizations will collaborate on construction of the first phase of a mining-metallurgical complex with an annual output capacity of 30,000 tons of nickel and cobalt at Punta Gorda. The approximate distribution of credits for the projects was 52 million rubles (US$63.18 million) for rehabilitation of Nicaro and Moa Bay and 15 million rubles (US$18.225 million) for the Punta Gorda complex. The ultimate investment needed to raise Cuban production to 90,000 tons of nickel annually was estimated at $600 million, not including the funds required for the infrastructure, housing, and energy.

Dominican Republic.—The ferronickel plant of Falconbridge Dominicana C. por A. was officially inaugurated by His Excellency Dr. Waukeen Balenguer, President of the Republic. The plant produced about 46,000 tons of ferronickel during the year, approximately 70% of its rated annual capacity.

Greece.—Société Minière et Métallurgique de Larymna S.A. (LARCO), the only active nickel producer in Greece, engaged in an expansion program designed to increase its nickel productive capacity from 1,100 to 1,750 tons per month.

Indonesia.—Indonesian production of nickel in 1972 was stimulated by a pricing dispute between Japanese consumers and the nickel producers in other areas of the Pacific. With Japanese help, PN Aneka Tambang (Aneka), the state mining corporation, was building a smelter at Pomalaa to process low-grade (1.8% nickel) laterite to 22% ferronickel. P.T. International Nickel Indonesia, a wholly owned subsidiary of INCO, announced agreement with six Japanese companies for equity participation in its planned nickeliferous laterite mining and processing facilities on the island of Sulawesi. The Japanese companies are to provide sales of the ferrous laterite mining and processing facilities project output over a 15-year period. It is expected that INCO's equity in the project will be 60% and that of the Japanese participants 20%; the remainder will be held by Indonesians.

New Caledonia.—Nickel ore production in New Caledonia in 1972 was 2% less than that produced in 1971 because a disagreement on prices with Japanese consumers shut down a large segment of the independent nickel mining industry. However, ore mining by that segment of the industry producing for processing in New Caledonia increased. Overall nickel production was down 4% compared with that in 1971, but ferronickel and matte production increased 28% and 25% respectively. Nickel ore exports to Japan were 42% less than exports in 1971.

The high level of production of nickel products in New Caledonia was maintained with the help of a group of consumers in France that, under French Government guidance, established a nickel stockpile of 38 million pounds.

The worldwide imbalance between nickel supply and demand delayed some planned nickel projects in New Caledonia and caused revision of others. The agreement

[e] Estimate. [p] Preliminary. [r] Revised.

[1] Insofar as possible, this table represents mine production of nickel. Where data relate to some more highly processed form, the figures given are used in lieu of actual reported mine output as a measure of mine output. The following table gives metallurgical plant output, including data for countries that mine no nickel, but that process imported ores, concentrates, and/or other crude materials.

[2] In addition to the countries listed, Albania and East Germany also produce nickel from mines, but available information is inadequate to make reliable estimates of output levels.

[3] Refined nickel and nickel content of oxides and salts produced, plus recoverable nickel in matte and concentrates exported.

[4] Includes a small amount of cobalt not recovered separately.

[5] Nickel-cobalt content of metallurgical plant products, plus recoverable nickel-cobalt in exported ores.

[6] Reported erroneously as refined metal in previous editions.

e Estimate. p Preliminary.

[1] Refined nickel plus nickel content of ferronickel produced from concentrates unless otherwise specified.

[2] In addition to the countries listed, East Germany and North Korea are believed to produce metallic nickel and/or ferronickel, but information is inadequate to make reliable estimates of output levels.

[3] Includes nickel content of nickel oxide and nickel fonte.

[4] Nickel-cobalt content of ferronickel only (no refined nickel is produced).

[5] Includes electrolytic nickel as follows 1970—14,763; 1971—17,077; 1972—18,189; the difference between these figures and the listed total is the nickel content of ferronickel, nickel oxide and nickel fonte.

[6] Nickel content of ferronickel and matte.

[7] Electrolytic nickel only.

between Société Le Nickel, S.A. and Patiño Mining Corp. to build a powerplant, erect a town, develop a harbor and port, and build a smelter in Poum on the northern tip of the island was allowed to lapse. However, Patiño entered an agreement to continue the project with Pechiney Ugine Kuhlmann (PUK) of France and the Gränges Co. of Sweden. The three concerns formed Société Metallurgique de Nickel Patiño Pechiney Gränges (SOMMONI), a new company that will manage the work. The Patiño subsidiary Compagnie Française d'Entreprises Minères, Métallurgiques et d'Investessiments (COFREMMI) was to own 42% of SOMMONI: PUK, 38%; and Gränges, 20%.

The French Government negotiated with three other concerns for mining lateritic nickel ores of New Caledonia: (1) International Nickel Co. of Canada, Ltd., which was attempting to organize a project for the production of 45 million pounds of nickel and 3 million pounds of cobalt annually, (2) Penamax, formed by American Metal Climax, Inc., and (3) Société Nationale des Pétroles d'Aquitaine of France and Freeport Minerals Corp. of the United States. At yearend none of the three potential projects were approved.

Philippines.—Marinduque Mining and Industrial Corp. (MMIC) announced that it was selling $3 million worth of its stock to raise the money needed to complete its equity share of the capital required to construct a laterite mining plant on the Surigao mineral reservation. Apparently the project was still viable despite numerous delays and the dampening effect of the world imbalance between supply and demand.

Atlas Consolidated Mining and Development Corp. began testing a 1,000-ton, bulk sample of Palawan ore preliminary to exercising its right of first refusal to exploit the properties. Reportedly, Soriano and Co. has proved reserves of 284 million tons containing 1.29 to 1.42% nickel at Palawan. Japanese companies negotiated for 1,000 tons of nickel concentrate per year from the Palawan deposits.

TECHNOLOGY

The pattern of nickel research and development in 1972 was little changed from that of the last 2 years. Scientists at Bureau of Mines laboratories researched methods of recovering nickel and copper from the Duluth gabbro of Minnesota. One element of the overall investigation was a study looking to pressure leaching of nickel-bearing gabbro in situ. The plan was to fracture the gabbro with nuclear explosives.

In the oxide ore phase of the Bureau's extractive research program, metallurgists studied segregation and chloridization processes. They reported a simple, low-cost roasting modification for improving nickel and cobalt extraction from relatively refractory, low-grade, weathered serpentine. The process was described in a Bureau of Mines Technical Progress Report.[3]

Apparently the pattern of research in the U.S.S.R. has followed that of the free world. It was reported that nickel production had been increased 37% in the 5-year plan period between 1966 and 1970. The increase was due to introduction of new technology, automation, mechanization, improvements in processes, and modernization of mining and metallurgical equipment. Oxygen-enriched airblast into a shaft smelting furnace, autoclave leaching to increase production of nickel hydroxide, and replacement of multiple hearth roasters by closed-system fluo-solids furnaces were among the technical improvements.[4]

The Division of Mineralogy of the Australian Commonwealth Scientific and Industrial Research Organization (CSIRO) began a comprehensive investigation on the nature of deposition and mode of origin of the nickel sulfide ores of Australia. The program was designed to develop a genetic model that is consistent and adequately understood. The initial work was an interpretive study of nickel-iron sulfide ore in the Lunnon shoot at Kambalda, Western Australia.[5] A magmatic model for the formation of the shoot was developed as a result of study of one intersection of the ore body. The data suggested that at temperatures above 1,140° C, the ore and its host ultramafic rock consisted of a crystal mush containing olivine and chromite crystals, sulfide droplets, and silicate magma.

CSIRO researchers also began collecting representative samples of nickeliferous oxide ores from various Australian deposits to determine their response to known hydrometallurgical procedures.[6]

Mining engineers of INCO, reported on more than 10 years of progress in raise boring at the Sudbury district nickel mines.[7] Improved safety in ground control, lower resistance to air flow, and reduced cost were cited as the advantages in raise boring.

The Republic Steel Corp. of Cleveland, Ohio, reported a new hydrometallurgical process for recovering nickel.[8] Metallurgists of the company worked with the Colorado School of Mines Research Institute on a feasibility study and pilot plant operation to test a number of lateritic ores. They reported that using hydrometallurgical techniques at elevated temperatures with additives of sulfur, oxygen, and metallic iron, the new process achieved 92% nickel recovery.

Informal reports from industrial research laboratories indicated a high level of activity in the search for new nickel applications, but as in 1971, the intensified research was not reflected in the published literature. Armco Steel Corp. described a new 5% nickel alloy to compete with ferritic and austentic nickel stainless steel.[9] The 5% nickel steel was said to increase the versatility of the nickel steels in handling and storage of liquified gases with special emphasis on liquid natural gas (LNG). Most LNG facilities have been built of alloy steels containing 9% nickel.

Nitrogen

By Ted C. Briggs [1]

Domestic production of fixed nitrogen increased by 2%, while production of elemental nitrogen increased by 15% in 1972. Domestic ammonia plants produced at about 84% of their total capacity.

Farmland Industries, Inc., announced plans to build an ammonia plant near Enid, Okla.

Exports of major nitrogen compounds surged upward in 1972, with a 31% increase above 1971 exports and an $81 million increase in value of the exports. There was little overall change in total imports. A large increase in urea imports was partially offset by a sharp drop in imports of sodium nitrate.

DOMESTIC PRODUCTION

Production of fixed nitrogen increased by 2% in 1972, but this percentage should be viewed with caution since final production figures have, in general, been revised upward at later dates. About 33,000 standard cubic feet of natural gas was required to produce 1 ton of anhydrous ammonia; therefore, about 470 billion standard cubic feet of natural gas was used to produce synthetic ammonia in 1972. The production of ammonia accounted for roughly 2% of the domestic consumption of natural gas. Domestic ammonia plants produced at about 84% of the total maximum domestic capacity, up from 81% of capacity in 1971. All of the domestic plants combined will probably have difficulties producing at a combined rate much over 90% of capacity. It can be seen, therefore, that production moved toward effective capacity during 1972. The production of elemental nitrogen jumped by 15% in 1972.

Farmland Industries, Inc., announced plans to build an ammonia plant near Enid, Okla. Capacity was scheduled to be 380,000 tons per year when the plant comes onstream in 1974, and natural gas feedstock for the plant was to be supplied by Oklahoma Natural Gas Co. Mid-America Pipeline Co., Inc. (MAPCO) planned to construct a 6-inch-diameter pipeline, 115 miles in length, from the Farmland Industries plant to MAPCO's existing ammonia pipeline southwest of Hutchinson, Kans. Farmland Industries also announced plans to construct 30,000-ton ammonia storage terminals in Nebraska, Iowa, and Minnesota. Total cost of the Farmland Industries project was expected to exceed $30 million.[2]

CF Industries, Inc. was planning to build a 1,000-ton-per-day urea plant at its Donaldsonville, La., nitrogen complex where the company now operates two 1,000-ton-per-day ammonia plants. Also, the company planned to add regional warehouses for urea at four locations, with a total capacity of 100,000 tons.

Later in the year, property owners adjacent to the proposed urea plant location took legal steps to enjoin construction of the plant on the basis of possible noise from the plant, the visual appearance of the plant, and possible emissions. No disposition of the dispute had been made at yearend.[3]

Shell Chemical Co. planned to drop out of the fertilizer production business with the closures of its ammonia and nitrogen products plants at Ventura, Calif., and St. Helens, Oreg. Reasons given for the closures were an oversupply of ammonia, spiraling operating cost, technological obsolescence and small production capacity of the plants, and shortage of natural gas feedstock. Later, Shell reached a tentative agreement with Reichhold Chemicals, Inc. for Reichhold to purchase the St. Helens, Oreg., facilities. Production capacity at St. Helens was 80,000 tons per year of ammonia and 50,000 tons per year of urea.[4]

Vicksburg Chemical Corp. planned to reopen the potassium nitrate plant formerly owned and operated at Vicksburg, Miss., by American Metal Climax, Inc. (AMAX).[5]

Air Products & Chemicals, Inc., filed a legal action against United Gas Pipe Line Co. Air Products was seeking a declaratory judgment limiting the prices to be charged under a long-term natural gas supply contract. An injunction was also being sought to assure continued natural gas service while the matter was in litigation. United Gas supplied natural gas feedstock to Air Products' Escambia, Fla., plant which produced ammonia, methanol, and other industrial chemicals.[6]

American Cyanamid Co. discontinued its sales of high explosives, blasting caps, and related products. Low profit margins, a declining market, and rising cost of distribution and security were cited as reasons for the decision. The company planned to continue to sell ammonium nitrate for agricultural and blasting agent uses.[7]

Gulf Central Storage and Terminal Co. announced plans to build four refrigerated storage tanks for anhydrous ammonia. The tanks will be located at Iowa Falls and Algona, Iowa; Aurora, Nebr., and Crawfordsville, Ind., and each tank will have a capacity of 30,000 tons. Five additional pump stations were to be added in the Gulf Central pipeline system.[8]

CONSUMPTION AND USES

The principal end use for fixed nitrogen materials in 1972 was, as usual, for fertilizers. Fertilizer usage accounted for about 74% of the domestic fixed nitrogen consumption. Environmentalists and ecologists continued their efforts to limit the use of nitrogen fertilizers, but various other studies have found no evidence of danger to man, animals, or the global environment from present patterns of nitrogen fertilizer usage. Also, the Illinois Pollution Control Board, after nearly a year of public hearings, rejected attempts to severely curtail fertilizer usage.[9]

One very important, but rarely mentioned, class of nitrogen compounds was the surface-active agents. The basic chemicals are primary amines obtained when fatty acids are reacted with ammonia. The largest single use of these materials was for fabric softeners. Another important use of surface-active agents was in herbicides and insecticides in order to make the pesticides cling to the plants and prevent them from being washed away by rain or dew. Surface-active agents were used in agriculture as anticaking agents in fertilizers. The amount of surface-active agents required to impart anticaking properties was small, approximately 0.5 weight-percent.

In the textile industry, the nitrogen-containing surface-active agents were used in the formulation of antistatic spinning oils, as softeners, as dye-leveling and retarding agents, and as dye fixatives. In the bituminous road construction industry, surface-active agents were used as adhesion agents to prevent a water barrier from forming when the hot bitumen comes into contact with stone surfaces during road construction.

Surface-active agents were used extensively in mineral ore beneficiation. The first big industrial application of aliphatic amine salts was for the flotation of potash. Amines have a peculiarly strong affinity to any form of silicon surfaces, and amine collectors were used for the enrichment of silica sand for glass factories. Also, amines were used to produce a high-quality white clay for paper coating, and were used to remove silica from iron ore. In the petroleum industry, surface-active agents were used in drilling fluids, as corrosion inhibitors, as de-icers and antistalling agents in gasoline, in diesel and domestic fuel oils to inhibit oxidation and polymerization, as acid scavengers, and to keep small solid particles in suspension.[10]

Under pressure from some members of Congress and from consumer advocates, the Food and Drug Administration (FDA) placed mild restrictions on the use of sodium nitrite as a food additive. Sodium nitrates and sodium nitrites have been used for many years as food additives to prevent red meat from turning brown, to impart the red color to cured meats, and to retard development of the microorganism clostridium botulinum which, when it grows in food and is ingested, becomes an acute food poison marked by a high mortality rate. The criticism of sodium nitrite usage as a food additive resulted from some scientific data that indicated the sodium nitrite could react with secondary and tertiary amines under certain conditions to form some nitrosamines that have been found to be carcinogenic in test animals. The FDA thus had the difficult choice between a possible risk of cancer or the very real hazard of botulism. The new restrictions remove the chemical from food uses which were deemed nonessential.[11]

PRICES

In general, prices of major nitrogen compounds increased or, in some instances, remained stable during 1972. The following are samples of pricing actions during 1972.

Vistron Corp.'s price for agricultural ammonia was set at $59.40 per ton on April 1, 1972, for ammonia delivered to all States east of the Continental Divide, except Montana, New York, Pennsylvania, Maryland, New Jersey, West Virginia, North Carolina, South Carolina, Virginia, and the New England States. For roughly the same geographical area, W. R. Grace & Co. and Wycon Chemical Co. set the delivered tankcar price for ammonia of $60 per ton into effect on February 1, while Olin Corp. established a listing of $57 per ton, same basis.

Vistron Corp.'s prices for low-pressure nitrogen solution (37% nitrogen, in tankcar lots) was set at $120 per ton of contained nitrogen or $44.40 per ton of product, f.o.b. Lima, Ohio, freight equalized against the delivered cost of the same solution shipped from approved competitive shipping points.

American Cyanamid Co. set new schedules, effective July 1, 1972, for ammonium nitrate fertilizer. The bulk price of ammonium nitrate prills to fertilizer manufacturers was set at $45 per ton f.o.b. South River, Mo. The delivered price in bulk 50-ton carlots was $47 per ton. Generally the delivered price applied to customers in the Midwest and South. A delivered price of $51 per ton was quoted for bulk material in 50-ton carlots from Port Robinson, Ontario, Canada, and applied to customers in New England, the East, and the Southeast. Monsanto Chemical Co. announced similar prices for ammonium nitrate.

W. R. Grace & Co. announced a price for direct application anhydrous ammonia of $60 per ton on August 1, 1972, the price included delivery by truck or rail to the New England States, New York, New Jersey, Pennsylvania, Maryland, West Virginia, Virginia, North Carolina, and South Carolina. Delivered prices in States east of the Continental Divide, excluding Montana, Georgia, Florida, and the other States previously listed, was $55 per ton. Announced price for urea (45% nitrogen) was $58 per ton f.o.b. Woodstock, Tenn. Delivered price for urea in 50-ton carlots was $61 per ton, while minimum car and trucklots were set at $65 per ton. Urea (46% nitrogen) was $2 per ton higher.

Vicksburg Chemical Co. announced delivered bulk prices from $91 to $103 per ton, depending on the delivery zone, for potassium nitrate. Prilled material was $4 per ton higher and an additional $8.50 per ton was charged for material packaged in bags of 100-pound capacity.

H. J. Baker & Bro., Inc., issued a new price list, effective July 7, 1972, for its po-

Table 5.—Price quotations for major nitrogen compounds in 1972

(Per short ton)

Compound	Jan. 1	Dec. 25
Ammonium nitrate, domestic, fertilizer-grade, 33.5% nitrogen, bulk, delivered	$47–$49	$47–$49
80-pound bags, same basis	47–54	47–54
Ammonium sulfate, standard-grade, commercial, bulk, f.o.b. works	[1] 15–27	--
Anhydrous ammonia, fertilizer, wholesale, tanks, delivered east of Rockies, except East Coast	55–65	55–65
Aqueous ammonia, 29.4% NH_3, anhydrous basis, tanks, freight equalized, east of Rockies	65–70	65–70
Delivered east coast	60–65	60–65
Sodium nitrate, domestic, agricultural, bulk, carlots, f.o.b. works	51.50	51.50
Bags, carlots, f.o.b. works	55.50	55.50
Sodium nitrate, imported, commercial, bulk, carlots, f.o.b. Atlantic and Gulf warehouses	51.50	51.50
100-pound bags, carlot, same basis	55.50	55.50
Urea:		
Industrial, 46% nitrogen, bulk, 50-ton carlots, delivered East	64–76	64–76
Agricultural, 46% nitrogen, bulk, same basis	62–63	62–63
Agricultural, 45% nitrogen, bulk, 50-ton carlots, delivered East	60–61	60–61
Diammonium phosphate, fertilizer grade, 18–46–0, bulk, carlots, f.o.b. Florida works	55–66	55–66
Bags, same basis	61–73.50	61–73.50

[1] Chemical Marketing Reporter. Agricultural Chemicals. V. 201, No. 21, June 5, 1972, p. 23.

Source: Chemical Marketing Reporter.

tassium nitrate which was imported from Israel. Bulk price was set at $87 per ton f.o.b. cars and trucks at warehouse. Prilled material was priced at $91 per ton with a charge of $8.50 per ton extra for bagged material.

Hooker Chemical Corp. announced new prices for anhydrous ammonia of $67 per ton f.o.b. its Tacoma, Wash., plant with freight allowed to destinations in the States of Washington and Oregon and west of the Cascade Mountains. The prices were for agricultural and industrial consumers (except for the paper and pulp industry).[12]

Urea prices firmed during the year because of increased consumption and, in part, because of the closures of a 250,000-ton-per-year plant of E. I. du Pont de Nemours & Co. and a 190,000-ton-per-year plant of Allied Chemical Corp.[13]

FOREIGN TRADE

Exports of major nitrogen compounds surged upward in 1972, with a 31% increase in the total amount of contained nitrogen exported and an $81 million increase in value of the exports. Increased exports were due to the effects of devaluation of the dollar, strong international demand and prices for nitrogenous fertilizers, domestic price ceilings, and technical problems which delayed the startup of new ammonia plants in several areas of the world. Exports are expected to decline as domestic demand moves into balance with domestic capacity.

On a contained nitrogen basis, total imports increased by only 4%. The most significant changes in the import pattern were a 70% increase in urea imports and a 44% drop in sodium nitrate imports.

WORLD REVIEW

The most significant development in the world market for nitrogenous fertilizers was the change from a large oversupply situation at the beginning of the year to a market with increasing prices and localized shortages of some types of fertilizers by yearend. While world production of fixed nitrogen did not increase dramatically, there was a significant reduction in stocks of nitrogenous fertilizers carried over from the previous year. A factor which contributed to tight supplies in some areas was a rather widespread malfunctioning of new ammonia plants that were scheduled to come onstream during the year.

Eastern Europe consolidated its position as the world's leading area for the production of fixed nitrogen, and the People's Republic of China, and India continued to be the world's leading importing countries with combined imports of 35% of the nitrogenous fertilizers traded in the international markets.[14]

Australia.—Austral-Pacific Fertilizers Ltd. merged with Eastern Nitrogen Ltd. into Consolidated Fertilisers Ltd. Shareholders in the new firm were Imperial Chemical Industries of Australia & New Zealand Ltd. (ICI Australia) with 37.7%, The Dow Chemical Co. with 19.8%, Swift and Co. with 13%, Sulphide Corp., which was a subsidiary of Conzinc Rio Tinto Australia Ltd., with 9%, King Ranch Australia with 3.9%, Mitsui & Co. with 2.3%, and others with 14.3%. The consolidated group faced the basic problem that Australia had about twice as much fertilizer capacity as the domestic market could absorb.[15]

Brazil.—Ammonia production in Brazil was based mainly in the central and northern sectors. There were two plants in Cubatao, São Paulo. One of these started production in 1959 and had a capacity of about 10,000 tons per year. This plant used refinery gas as a feedstock. The other plant started production in 1970 with a capacity of 120,000 tons per year while using naphtha as the feedstock. A third plant at Camacari, Bahia, had a capacity of 47,000 tons per year with production starting in 1971. Brazilian production cost did not, however, allow domestic ammonia to compete very well with imported ammonia. For example, imported ammonia was available at $50 per ton, while domestic ammonia sold for $90 per ton.[16]

Canada.—DuPont of Canada, Ltd. began construction of a commercial explosives plant at Ashcroft, British Columbia. The plant, estimated to cost $4 million, was expected to be onstream in 1973. The plant will produce newly developed explosive products.[17]

Chile.—A new grade of Chilean potash nitrate was introduced. The new product had an analysis of 15% N, 14% K_2O equivalent, and 18% Na. Price of the new grade was adjusted to take account of the additional value, but price per unit of plant food remained unchanged.[18]

Czechoslovakia.—A 1,000-ton-per-day ammonia synthesis unit and a 15,000-ton ammonia storage unit were delivered by Friedrich Uhde G.m.b.H. of Dortmund, West Germany, to the Duslo plant, of Sala, Nad Vahom. The delivery included six compressors designed by the Swedish company Stal Refrigeration AB, of Norrkoping.[19]

A 200,000-ton-per-year urea plant at Zaluzi near Most in Czechoslovakia was expected to start production at midyear.[20]

A 300,000-ton-per-year fertilizer granulation plant was to be built at Bratislava, by French engineering companies. Ammonia, ammonium nitrate solution, urea, and superphosphate were to be brought in by rail.[21]

Finland.—Typpi Oy, the country's nitrogenous fertilizer producer, operated state-owned plants for the production of ammonia, urea, nitric acid, and compound fertilizers. Plants are located at Oulu near the head of the Gulf of Bothnia in northern Finland. The ammonia plant was said to be the most northerly in the world.

Ammonia capacity was 1,000 tons per day and the plant was designed by Humphrey's & Glasgow of the United Kingdom. Another older ammonia plant was converted for methanol production. Part of the ammonia production was converted to urea in a plant with a capacity of 100,000 tons per year.

A large export market for Finnish urea was the People's Republic of China.

Typpi Oy produced a high-analysis compound fertilizer by digesting low-grade phosphate rock with nitric acid and extracting the resulting fertilizer material with tertiary amyl alcohol.[22]

France.—An air separation plant with a capacity of 1,400 tons per day of nitrogen was brought onstream by l'Air Liquide at Fos-sur-Mer, near Marseille. Nitrogen production was divided into 340 tons per day of high-purity nitrogen, 940 tons per day of 99% purity nitrogen, and 120 tons per day of liquid nitrogen.[23]

A nitric-acid-based fertilizer complex was started at Montoir-de-Bretagne near St. Nazaire. The plant was to produce 600 tons per day of ammonium nitrate, 150 to 200 tons per day of compound granulated fertilizers, and 30,000 tons per year of liquid fertilizers.[24]

Germany, East.—The East German Industrie Import Anlagen signed a contract with the Polish trade organization, Budinex, for the planning and construction of an oil pipeline to link the East German petrochemical complexes at Schwedt and Leuna. Leuna was the traditional center of East German nitrogen production which supplied over 500,000 tons per year of ammonia. The most significant development at Leuna was the gradual conversion of ammonia plants to petroleum feedstock. Previously all of the ammonia units at Leuna were based on lignite supplied from nearby coal workings. Schwedt was also an important center for the production of fertilizers, and gases from a large petroleum refinery located there were used as feedstock for ammonia production.[25]

Germany, West.—Domestic consumption of nitrogenous fertilizers increased while domestic production and exports declined. Imports of ammonium nitrate, ammonium sulfate, and urea supplied the 4% increase in domestic consumption. The bulk of the imports came from East European countries and sold at prices 3% or 4% below the domestic prices. Exports of nitrogenous fertilizers declined; consequently production was expected to drop, with some production units operating at 70% of capacity or less.[26]

Greece.—The fertilizer plant at Ptolemais of Nitrogenous Fertilisers Industry S.A. was to expand its capacity by the installation of units with capacities of 580 tons per day of ammonium sulfate, 440 tons per day of ammonium nitrate, and 230 tons per day of nitric acid.[27]

A battle took place through the Greek press over the decision of the state-owned Nitrogenous Fertilisers Industry S.A. to expand its lignite-based ammonia facilities. In a series of open letters to the Prime Minister in the Athens Daily Post, an opponent of the project called for a reassessment because he claimed the method for producing ammonia from lignite was outdated and economically unjustifiable.

In reply to arguments against the project, the Board of Directors of the Nitrogenous Fertilisers Industry issued a lengthy statement in the same newspaper. The Board of Directors said that the plants were a national industry of public utility, a medium of application of rural policy of the Government, and not an enterprise in which the state expected some short-term profits. Also, the Board stated that the exploitation of local lignite was a national duty. Greece, lacking sources of liquid fuels and natural gas, had based its policies on the utilization of local resources and was continuing to follow this policy despite high investment cost.[28]

India.—The Indian Government's crash program to raise an additional 16.5 million tons of grain aggravated the Nation's chronic fertilizer shortage. Meeting the grain quota added 480,000 tons to India's nitrogen fertilizer requirements.

For future fertilizer supplies, India signed contracts with foreign producers and planned expansions of domestic fertilizer plants. A $14.4 million contract was signed with the Japan Ammonium Sulphate & Urea Export Co. Ltd. for 200,000 tons of urea. Contracts were signed for 460,000 tons of urea from Bulgaria for future delivery, and negotiations were underway with Kuwait for 350,000 to 500,000 tons of urea and 250,000 tons of liquid ammonia.

Mangalore Chemicals and Fertilizers started construction of an $80 million ammonia and urea complex based on naphtha feed stock. The plant location is at Panambur, in Mysore State, in southern India, and Mangalore had been licensed to produce 220,000 tons per year of ammonia and 340,000 tons per year of urea.

Also, India was shopping in the Soviet Union and Czechoslovakia for equipment for coal-based fertilizer projects planned for Korba, Talcher, and Ramagundam. An Indian technical team returned empty-handed from an earlier shopping trip to the United States, Western Europe, and Japan.[29]

The Indian Ministry of Petroleum and Chemicals continued to put forward optimistic plans for future fertilizer production, and plans were presented to double nitrogen fertilizer capacity by 1979. India hoped to achieve self-sufficiency in nitrogen fertilizers by 1977, but, historically, earlier plans have failed to meet stated goals. For example, a capacity to produce 3 million tons of nitrogen in fertilizers by 1974 was planned, but only 2.3 million tons of nitrogen capacity now seem possible and actual capacity may be below this amount.

At the beginning of the "Fourth Plan" nitrogen capacity was just over 1 million tons per year. Capacity was increased to 1.34 million tons per year in 1970–71, and during 1971–72 two new ammonia plants went into production which, together, increased capacity to 1.53 million tons per year.

The ministry pointed out that if its assumptions prove to be invalid, then production will be set back. The supply of power at Nongal was one important factor which was assumed. A second assumption was that production would not suffer because of labor problems.[30]

Indonesia.—P. T. Pupuk Sriwidjaja, Indonesia's Government-owned petrochemical company, selected M. W. Kellogg Co. as general contractor for the major portion of an $84 million fertilizer and petrochemical complex to be built on the Musi River near Palembang, in southern Sumatra. Kellogg will have responsibility for the erection of all process and offsite facilities except for gas gathering and transmission.

The plans called for the erection of a 660-ton-per-day ammonia plant which Kellogg will design and engineer, and a 1,150-ton-per-day urea plant using the design of Mitsui Toatsu Co. which will be engineered by Toyo Engineering Co. of Japan. The plant will use 42 million standard cubic feet per day of natural gas feedstock, which will be piped approximately 70 miles from Sumatran natural gasfields.[31]

Ireland.—Nitrogin Eireann Teorata of Ireland awarded a contract in excess of $2.6 million for the expansion of its calcium ammonium nitrate facilities at Arklow, County Wicklow. Woodall-Duckham Ltd., of the United Kingdom, was the selected contractor and the Kaltenback process was to be used. Plant capacity will be 150,000 tons per year.[32]

Italy.—A subsidiary of Italy's state-owned energy group brought onstream one of the largest ammonia and urea complexes in the world. Ammonia capacity was 1,500 tons per day, and urea capacity was 1,100 tons per day. The site of the new plants was at Monfredonia in the Mezzogiorno, Italy's southern development area. Because the complex is located in an area with scarce water supplies, extensive use was made of air coolers and condensers.[33]

Japan.—Signs pointed, for the first time in 5 years, to an improved outlook for Japan's chemical fertilizer industry, mainly because of improvements in exports. The Japan Ammonium Sulphate & Urea Export Co. Ltd. reported that, at the end of the fertilizer year, the country's two most important chemical fertilizers, ammonium sulfate and urea, had stockpile reductions of 300,000 and 550,000 tons, respectively. The reduction in stocks was due to unexpected growth in demand for fertilizers in India, Mexico, and other countries in Southeast Asia and Latin America.[34]

[32] Chemical Marketing Reporter. Ammonium Nitrate Project. V. 201, No. 19, May 8, 1972, p. 7.

[33] Chemical Marketing Reporter. Ammonia-Urea Facility Is Opened by Italy's ANIC. V. 202, No. 26, Dec. 25, 1972, p. 3.

The Japan Ministry of Trade and Industry (MITI) urged Japanese fertilizer producers to make a gradual retreat from world fertilizer export markets. While acknowledging Japan's current share of the fertilizer export markets, MITI had strong doubts about the long-term prospects in this sector. MITI predicted that ammonia demand would grow only slightly and that existing Japanese ammonia plants will only be operating at 86% of capacity in 1976. Old plants should be closed and no new capacity was necessary according to MITI. MITI said that around 770,000 tons per year of urea capacity should be scrapped to reduce the current 70% to 80% dependence on export markets.[35]

Mitsubishi Katoki Kaisha commissioned a large coal gas distillation plant at the Sakaidi, Kanagawa complex of Mitsubishi Chemical Industries. The new plant employed U.S. Steel Corp.'s Phosam ammonia recovery process which separated ammonia, benzene, and fuel gas from coal gas.[36]

Japanese producers of caprolactam, coke, and synthetic resins started moves to cut back production of byproduct ammonium sulfate by introducing new processes. Nearly all Japan's ammonium sulfate was produced as byproduct material, and in 1972 production of byproduct ammonium sulfate was over 2 million tons.

Ube Industries Ltd., Japan's largest producer of caprolactam, planned to use Dutch State Mines technology to reduce ammonium sulfate production from 4.2 tons to 1.7 tons per ton of caprolactam produced.

Mitsubishi Chemical Industries and Nippon Steel Corp. adopted new coke production processes which do not produce ammonium sulfate. Also, Mitsubishi Chemical Industries applied for a loan to finance a new methyl methacrylate unit to cut byproduct ammonium sulfate production.[37]

Japan's fertilizer industry enjoyed a sharp rise in demand and price improvements after 3 sluggish years. Orders and inquiries were received from Mexico, El Salvador, India, Brazil, China, and other countries. Japanese fertilizer producers rejected a number of inquiries because the prices proposed by potential buyers were considered too low. In the past, about 60% of Japan's fertilizer exports went to China.[38]

Mexico.—A joint venture group consisting of Celanese Mexicana, Nylon de Mexico, Dutch State Mines, and the Credits Buratil of the Mexican bank commissioned its 40,000-ton-per-year caprolactam plant at Salamanca, Mexico. Dutch State Mines, which holds a 23% interest in the operation, supplied the plant process, and construction was carried out by Stamicarbon Corp. The plant was to provide a domestic source of caprolactam for the nylon operations of Celanese Mexicana at Taluca and Nylon de Mexico at Monterrey. Fibras Sinteticas, which recently expanded its nylon polymerization and spinning facilities at Monterrey with the aid of Vickers Zimmer, was also expected to take caprolactam from the new plant. Ammonia and cyclohexane for the new operation were supplied by Petróleos Mexicanos (Pemex) and the byproduct ammonium sulfate produced along with the caprolactam was sold to Guanos y Fertilizantes S.A.[39]

Pemex awarded a contract to the M. W. Kellogg Co. of the United States for the design and engineering of a 1,000-ton-per-day ammonia plant. In addition to the engineering, Kellogg was to be responsible for the construction, commissioning, and assistance in procurement of specialized equipment. The ammonia plant was to be built at the petrochemical complex at Cosoleacaque and will be the first large-scale ammonia plant in Mexico designed by Kellogg. Completion of the plant was scheduled for 1974, and the ammonia was to be used domestically.[40]

Netherlands.—Nederlandse Stikstof Mattschappij NV (NSM), a Belgian corporation, was a major factor in the Dutch chemical industry because all of the corporation's production plants are at Sluiskil near Terneuzen in the Netherlands. The corporation (NSM) was owned by Montecatini Edison, S.p.A. (Montedison) (69%), Imperial Chemical Industries Ltd. (25%), and the French steel group, Wender-Sidelor (6%). NSM started producing nitrogenous fertilizers in 1930 with coke oven gas as the feedstock. The company was the second largest producer of nitrogenous materials in the Netherlands in 1972. Ammonia was produced by NSM in three modern plants which used steam reforming of domestic natural gas to produce the required hydrogen, and capacity was 550,000 tons per year of contained nitrogen. The major part of the ammonia production was used internally for the production of nitrogenous fertilizers and technical nitrogen products. The plants are ideally located for export markets as they are along the Gent-Terneuzen Canal, which is accessible, through locks, to oceangoing vessels up to 60,000 tons. At NSM's own quay, more than 1 million tons per year of nitrogen-containing products were handled.

An unusual project, which was underway in the Netherlands during the year, was soil freezing with liquid nitrogen during the construction of an underground railway system in Amsterdam.[41]

Norway.—Additional production facilities at the Glomfjord Fabrikker fertilizer plant owned by Norsk Hydro A/S were to be completed by yearend. The expansion was to double the plant's capacity to produce calcium nitrate and complex fertilizers.[42]

Norsk Hydro started bulk transportation of calcium nitrate. During the year a ship destined for the United States took on board 6,000 tons of calcium nitrate, 9,000 tons of urea, and 3,000 tons of complex fertilizers at the port of Heroya. A company representative said that this was one of the largest bulk cargoes of fertilizers ever loaded on a single vessel, but that the long distance and the increasing cost of landing bagged cargo in American ports made bulk transportation necessary.[43]

Poland.—The Wloclawek fertilizer plant northwest of Warsaw was formally inaugurated and started to supply the northern Polish market. Plant capacity is 1,500 tons per day of ammonia, 1,800 tons per day of nitric acid, and 2,400 tons per day of ammonium nitrate. Feedstock for the plant is natural gas.[44]

Qatar.—The 330,000-ton-per-year ammonia plant of Qatar Fertilizer Co. entered the initial commissioning stage at Umm Said. Ammonia production was to commence in July and the 360,000-ton-per-year urea plant was to start operation by yearend. The plants were owned by the Qatar Government (63%), Norsk Hydro (10%), Hambros Bank (10%), and Power-Gas (7%). Natural gas feedstock for the plant was to come from Qatar's Western Duckham oilfield. Ammonia and urea from the plant were expected to be exported to Asia, East Africa, and the People's Republic of China.[45]

Rhodesia, Southern.—Sable Chemical Industries was reported to be commissioning its new ammonia plant at Que Que. An Australian producer was believed to have supplied the bulk of Rhodesia's ammonia requirements in the past by shipping material into Lourenço Marques and then by rail into Que Que for the production of ammonium nitrate. Shipments of Australian ammonia were expected to drop off as the Sable plant, believed to have a capacity of between 60,000 and 70,000 tons per year of contained nitrogen, entered into production.[46]

South Africa, Republic of.—A 1,000-ton-per-day ammonia plant was to be built at Midderfontein in South Africa by African Explosives & Chemical Industries, Ltd. The plant will be based on the use of coal feedstock, and a $50 million contract for the plant was awarded to the West German contractors, Heinrich Koppers G.m.b.H. Completion was scheduled for 1974.[47]

Spain.—At yearend, Spain had 12 plants with capacity to produce ammonia.[48] Their capacity in thousand tons NH_3 per year was as follows:

Company and location	*Capacity*	*Process*
Eiasa, Huesca	10	Electrolysis.
Sefranitro, Bilbao	90	Coking gas recovery.
Ensidesa, Aviles	107	Do.
Encaso, Puentes	22	Lignite gasification.
Nicas, Valladolid	60	Partial oxidation.
Cinsa, Gran Canaria	35	Do.
Encaso, Puertallano	198	Naphtha reforming.
Repesa, Cartagena	264	Do.
Aesa, Malaga	100	Do.
Inquitasa, Tarragona	20	Do.
Fertiberia, La Coruña	95	Do.
Fertiberia, Huelva	90	Do.
Total	1,091	

Unión Explosivos Rio Tinto awarded contracts for an ammonia and urea complex to be built at Seville, Spain. The ammonia plant was to have a capacity of 300,000 tons per year and will be based upon M. W. Kellogg Co. technology. Kellogg was to supply the engineering responsibilities for the plant, and construction was to be by the Spanish contractor, Tecnicas Reunidas. Startup of the plant was scheduled for 1975. Urea production was to be 165,000 tons per year and Mitsui of Japan was to supply the process. Toyo Engineering of Japan was to handle the engineering, while the Spanish contractor, Heredia y Moreno, was to do the actual construction. During the last two years Spain became a net importer of ammonia, but new production capacity was planned to meet Spain's rising demand.[49]

Nitratos de Castilla was to commission a new 100,000-ton-per-year complex fertilizer plant at Valladolid, Spain. The plant was to produce complex fertilizers containing 12% and 16% nitrogen. The new plant was the first to utilize a new nitrophosphate process based on a combination of the Kampka-Nitro process of the German company, Chemische Fabrik Kalk, and the continuous crystallization process of Severoceske Chemicke Zavady, Czechoslovakia. In the new process, slurry obtained from acidulation of phosphate rock was cooled to facilitate separation of calcium nitrate tetrahydrate by crystallization. The separated calcium nitrate tetrahydrate was converted into ammonium nitrate solution and pure calcium carbonate by a combination of carbonation and ammoniation in specially designed reactors. Ammonium nitrate solution was used for production of ammonium nitrate and calcium ammonium nitrate, or recycled to the fertilizer plant to increase the nitrogen content of the product.[50]

United Kingdom.—The use of a unit-train system by the British Oxygen Corp. (BOC) enabled it to offset the effects of inflation in the United Kingdom and to lower the price of nitrogen. The unit train was the heart of a complex distribution system with the objectives of making liquid elemental nitrogen available where required and making best use of production capacity. The main impetus for development of the system was the increasing congestion on roads in the United Kingdom and the increasing cost of energy.

The unit trains consisted of from 10 to 12 cryogenic tank cars, each with a 50-ton capacity. The trains were able to go anywhere in the system (primarily between Widnes, Sheffield, Wolverhampton, and Wembley) and back within 24 hours. There were 16 sources of nitrogen, storage at 32 points covering 21 demand centers, and a distribution center with 136 major routes.[51]

Fisons Fertilizers Ltd., was building an anhydrous ammonia storage tank at Avonmouth Docks, which was to have a capacity of 15,000 tons with an annual throughput of 120,000 to 150,000 tons.[52]

The United Kingdom cut by 60% the value of the subsidy paid to farmers for the use of fertilizers. Purpose of the cut was said to be a switch to European Economic Community methods and to require the farmer to recover the higher fertilizer cost through higher prices for consumer products. The effect of the subsidy cut was not clear at yearend, and it could simply result in a cut in fertilizer usage below the optimum level.[53]

Air Products Ltd. was to supply six vacuum-insulated nitrogen storage tanks each with a capacity of 54,600 liters. Three of these tanks were to be installed at the Hinkley Point B and three at the Hunterston B nuclear powerplants. The system was to provide gaseous nitrogen at 700 pounds per square inch and 250° C for injection, as required, into the reactors' coolant circuits. The gaseous nitrogen was to be obtained by vaporizing the liquid nitrogen withdrawn from storage.[54]

U.S.S.R.—A large fertilizer trade deal with the U.S.S.R. was proposed to Soviet officials by the chairman of Occidental Petroleum Corp. The proposal called for Occidental to supply 1 million tons per year of superphosphoric acid to the U.S.S.R. and to receive in return $150 million worth of urea and ammonia.[55]

Construction work at the Nevinomysk combine was going ahead smoothly, and nitric acid and ammonium nitrate units were being completed a year ahead of the original completion date. Two dilute nitric acid units were onstream, and a third unit was about to undergo trial runs. An ammonium nitrate plant with a capacity of 680,000 tons per year was commissioned during March, and an ammonia plant was expected to be onstream before yearend.[56]

Venezuela.—Venezolana del Nitrógen (Nitroven) was to supply urea fertilizer to the People's Republic of China from its new complex at El Tablazo, Venezuela. Two 900-ton-per-day ammonia plants and two 1,200-ton-per-day urea plants were commissioned at El Tablazo during the year. In addition, a 600-ton-per-day ammonia plant and 750-ton-per-day urea plant were started up at Morón. Two contracts were finalized with China for a supply of urea fertilizers worth $23 million. Nitroven expected to capture a 10% share of the world market for urea.[57]

TECHNOLOGY

A new processing method increased the polyphosphate content of nitrogen-phosphate fertilizers and increased the length of time that these materials could be stored. The method was developed and commercialized by the Tennessee Valley Authority. The new method consisted of mixing ammonia and superphosphoric acid, in nearly anhydrous conditions and at high temperature, in a pipe reactor. The initial exothermic reaction took place in the pipe at about 650° F and was complete in seconds. About 60% to 65% of the required ammonia was fed into the pipe reactor, and the remaining ammonia requirement was added in the storage tank. The final product was a liquid fertilizer which contained about 10% nitrogen and 34% P_2O_5 equivalent.

One user of the new process reported that the storage life of this type of fertilizer was increased from 2 weeks to 6 months. The increased storage life was due to the high polyphosphate content produced in the new method, as the polyphosphates sequestered impurities that formerly caused sludge precipitation.

An added advantage of the pipe-reactor process was that it accepted, as feedstock, a superphosphoric acid of lower initial polyphosphate content than other methods yet ended up with a higher grade product. Another advantage was that newly designed portable units could be located on farms or in farming areas. In these cases, ammonia and superphosphoric acid were to be fed directly from tank cars and thus eliminated the need for costly corrosion-resistant storage facilities.[58]

In most industrial caprolactam processes, each ton of caprolactam product was accompanied by 2 to 5 tons of byproduct ammonium sulfate. A new process was developed by Dutch State Mines (DSM) for making cyclohexanone oxime, a key precursor for caprolactam. The DSM process eliminated the production of ammonium sulfate with the oxime and thereby cut the byproduct ammonium sulfate from the overall process by 60%.

In classical caprolactam chemistry, a sequence of reactions yield hydroxylammonium sulfate which reacts with cyclohexanone under neutralization with ammonia to form cyclohexanone oxime and about 2.7 times as much ammonium sulfate as oxime. Subsequent processing of the oxime yields additional ammonium sulfate. The DSM process eliminates a large percentage of the ammonium sulfate by producing hydroxylamine and cyclohexanone oxime in a phosphoric acid buffered reaction. The hydroxylamine solution from the reaction contacts countercurrently with cyclohexanone in the presence of toluene, which acts as a solvent for the oxime produced. Hydrogen ions liberated by the reaction are accepted by the buffer system, and neutralization with ammonia, as in conventional oxime synthesis, is not necessary.

The new process was commercialized with the completion of three plants. One of the plants was in Japan, one in Britain, and one in the United States. Combined capacity of the three plants was 210,000 tons per year of caprolactam.[59]

Azote et Produits Chimiques S.A. of France developed a direct route to pure monoammonium phosphate, from which ammonium polyphosphate and diammonium phosphate could be prepared for agricultural or industrial use. In the process, phosphate rock was treated with nitric acid, and the resulting solution was passed to an extractor. In the extractor, isobutyl alcohol separated out the phosphates. After purification to remove calcium salts, the solution was neutralized with ammonia. The heavy phase from the resulting mixture was cooled and filtered to yield pure ammonium phosphate. The secondary stream contained calcium and ammonium nitrate. Upon recovery of the isobutyl alcohol, the calcium was removed as the carbonate and the ammonium nitrate solution was sent to a fertilizer prilling tower.[60]

A range of new thermoplastic materials, based on nitrile resins, was developed by Imperial Chemical Industries, Ltd., of England for the production of bottles for soft drinks and wine as well as for film and foil for packaging oxygen-sensitive food products. Bottles made from these nitrogen-containing resins were said to be tough and rigid and have low permeability to gases such as oxygen and carbon dioxide so that carbonated drinks contained in them had a long shelf life. The potential market for these materials is, of course, large.[61]

[60] Browning, Jon E. French Processes Paraded. Chem. Eng., v. 79, No. 22, Oct. 2, 1972, p. 34.

A coal gasification process, marketed by Koppers Co., was said to have the potential to relieve the developing shortage of natural gas. The Koppers-Totzek process used commercially proven technology to produce a gas rich in carbon monoxide and hydrogen that could be converted into fuel and process gases or synthetic natural gas of pipeline quality. The process was in operation in 16 plants around the world, primarily to gasify coal of all kinds to produce synthesis gas for ammonia production.[62]

The prilling process for manufacturing solid ammonium nitrate and urea gained worldwide acceptance since its introduction over 30 years ago. In the prilling process, a concentrated solution of ammonium nitrate or urea was sprayed from the top of a tall tower into a rising stream of air which cooled the droplets, which then solidify into spherical pellets.

There are two problems inherent in the prilling process. The first is that the large volume of cooling air used to solidify and cool the prills requires the installation of dust scrubbing equipment on the prilling tower to remove entrained dust. The second is the regulation of product size. The maximum prill size that can be obtained is limited by the economics of the tower height, 70 to 170 feet, required to provide sufficient free fall for solidification and cooling of the liquid spray. The size limitation is more serious with urea because of its lower melting point, 271° F, compared with 337° F for ammonium nitrate. Also, urea has a higher heat of crystallization, 104 Btu's per pound, than ammonium nitrate, 61 Btu's per pound.

Typical ammonium nitrate prills are 95% plus 16 mesh on a Tyler screen and about 65% plus 10 mesh. Urea prills are 95% plus 16 mesh and about 30% plus 10 mesh. These sizes and size distributions were said to be less suitable for bulk blending than product sizes obtained by granulation.

A number of studies have shown that segregation occurred when products having different size ranges were blended or handled. The greatest single factor in producing segregation was size distribution, while differences in shape or density had little effect. Granulated ammonium nitrate or urea, as contrasted with prills, is not limited to a particular size range that can be produced, and the size of granule produced can be regulated as desired by choice of suitable screen sizes.

Originally developed for the production of granular complex fertilizers, a C&I/Girdler, Inc., granulation process utilized the principle of accretion, or layering, to build up onionskin-like layers of ammonium nitrate or urea on small seed particles. This was accomplished by spraying a slurry or solution onto a rolling bed of solid particles in a rotating drum.

The C&I/Girdler, Inc., process differs from that used in most granulation processes. Other granulation processes depend on the agglomeration, or sticking together, of small particles by using a solution or slurry as the binding agent. The agglomeration method was found to be unsuccessful for the granulation of ammonium nitrate.[63]

Peat

By Eugene T. Sheridan[1]

Peat production in the United States decreased 5% in 1972, principally because a smaller number of plants were operating than in 1971. Production declined in 14 States, and active plants decreased by 17. The largest production losses were recorded in Florida, Indiana, Minnesota, and Pennsylvania.

Commercial sales, which were 5% greater than production because about 30,000 tons of peat was sold from stockpiles, were 1% greater than in 1971. The total value of sales also increased slightly because of the larger quantity sold and because of an increase of $0.03 per ton in the average value of all peat sold.

Imports increased 5%, and the quantity of peat imported in 1972 was about one-half the quantity produced domestically. Ninety-six percent of the peat imported was shipped from Canada.

World production was estimated at 89 million short tons. The U.S.S.R. was the largest producer with an output estimated at 80 million tons, 89% of the world total.

---

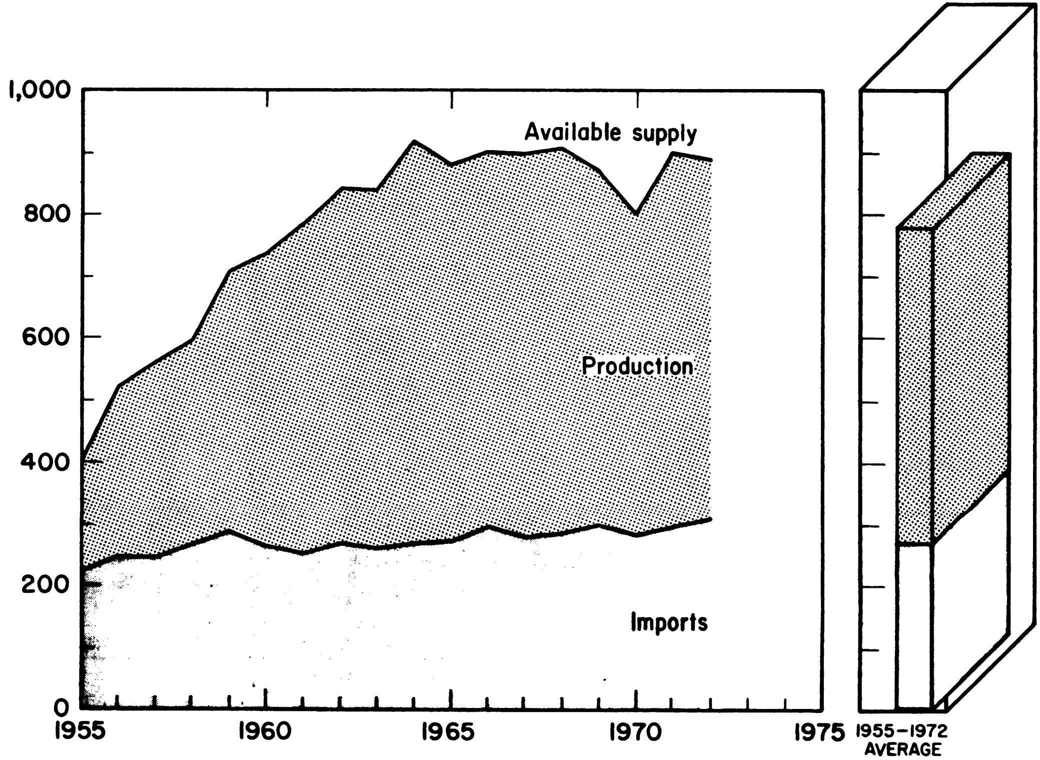

Figure 1.—Production, imports, and available supply of peat in the United States.

DOMESTIC PRODUCTION

The 5% decrease in production in 1972 resulted principally from a smaller output of moss peat and humus. This loss was partially offset by a 5% increase in reed-sedge production.

Twenty-two States produced peat in 1972 compared with 24 States in 1971. Michigan remained the largest producer with 36% of the Nation's output. Illinois, Florida, New Jersey, Colorado, California, and Indiana followed in output in the order named. These States, with Michigan, provided nearly four-fifths of the total production.

Table 4.—Relative size of peat operations in the United States

Size	1971				1972			
	Active plants		Production		Active plants		Production	
	Number	% of total	Short tons	% of total	Number	% of total	Short tons	% of total
Under 500 tons	29	24.1	5,868	1.0	26	25.2	6,142	1.0
500 to 999 tons	17	14.2	11,649	1.9	11	10.7	7,678	1.3
1,000 to 4,999 tons	44	36.7	93,949	15.5	38	36.9	86,279	15.0
5,000 to 14,999 tons	20	16.7	182,622	30.2	18	17.5	170,153	29.5
15,000 to 24,999 tons	4	3.3	67,388	11.1	6	5.8	111,240	19.3
Over 25,000 tons	6	5.0	243,906	40.3	4	3.9	195,220	33.9
Total	120	100.0	605,382	100.0	103	100.0	576,712	100.0

Active operations decreased from 120 to 103, but average output per plant increased 11% to 5,599 tons. Three-fourths of the operations, however, had outputs smaller than the average. Only 28 plants had production in excess of 5,000 tons, and only four plants produced more than 25,000 tons.

Roughly one-third of the peat was sold as produced with no processing other than air drying. Most of the remainder was shredded, and a small quantity was subjected to thermal drying.

CONSUMPTION AND USES

Commercial sales and imports both increased in 1972, and the amount of peat available for consumption was about 2% greater than in 1971.

Peat was used for a variety of purposes, but 85% of the total commercial sales reported by producers was for general soil improvement. Among the principal markets for this peat were nurseries and greenhouses, which used peat as a mulch and as a medium for growing plants and shrubs; landscape gardeners and contractors, who used peat for building lawns and golf course greens and for transplanting trees and shrubs; and garden, hardware, and variety stores, which sold peat to homeowners for mulching and for improving lawn and garden soils. Most of the remaining peat was sold for use in potting soils and for packing flowers and shrubs, but small quantities were used in mushroom beds and in mixed fertilizers and for earthworm culture and seed inoculant.

Fifty-four percent of the tonnage of peat sold commercially by producers was packaged. Packaged peat, however, accounted for more than two-thirds of the total value of sales. Of the total peat sold in packages,

about two-thirds was reed-sedge peat, about one-fourth was moss peat, and the remainder was peat humus.

States leading in sales of packaged peat were Michigan, Illinois, Indiana, and New Jersey, which, together, reported 84% of the total sales of packaged peat. Michigan was the largest producer of packaged peat with 55% of the total sales.

PRICES AND SPECIFICATIONS

Prices of peat at individual operations varied greatly in 1972, with the price depending mainly upon the kind of peat sold, the amount of processing, and whether the material was sold packaged or in bulk.

The overall average value per ton, f.o.b. plant, for peat sold in 1972 was $11.72. This was an increase of $0.03 per ton over the average value of 1971, and the bulk of the increase was attributed mainly to higher average receipts for peat sold by producers in New Jersey, Ohio, and Pennsylvania.

The average price of bulk peat increased $0.31 per ton to $8.19. Packaged prices, however, decreased an average of $0.20 per ton to $14.68. The average price for bulk peat was influenced mainly by higher overall prices for bulk sales by California, Pennsylvania, and South Carolina producers; the decline in the unit value of packaged peat was attributed to generally smaller receipts for each ton of packaged peat sold by Michigan producers.

Imported peat had a total value of $17.2 million. The total value of imported peat was 13% greater than in 1971, partially because there was 14,000 tons more peat imported but also because the average value per ton increased from $51.11 to $55.31.

Although the average value of imported peat was nearly four times that of domestically produced packaged peat, their values are not comparable because they are assigned at different marketing levels. Also, imported peat has different physical properties than most of the peat sold domestically, and it is usually sold on a volume basis rather than by weight. Each 100 pounds of a typical air-dried imported peat will measure approximately 12 bushels, whereas the same quantity of a typical domestic peat will measure 3 to 4 bushels. Only a few domestic operations produced peat with properties similar to those of the imported kind.

Peat is broadly classified in the United States as moss peat, reed-sedge peat, and humus, according to the materials from which it has been formed and its degree of decomposition. Moss peat is a type that has been formed principally from sphagnum, and/or other mosses; reed-sedge peat has originated mainly from reeds, sedges, and other swamp plants; and humus is peat too decomposed for identification of its biological origin.

FOREIGN TRADE

The quantity of peat imported into the United States in 1972 totaled 310,000 short tons. This was 5% more peat than was imported in 1971 and the largest quantity imported in any year to date.

Canada provided the bulk of the imports, supplying 96% of the total peat imported. Virtually all of the remaining foreign peat was supplied by Europe.

European shipments decreased 8%, principally because of smaller shipments from West Germany, Ireland, and Sweden. The decline in shipments from these countries, however, was partially offset by a substantially larger shipment from Poland.

Imported peat was classified according to

use as poultry-and-stable-grade peat and fertilizer-grade peat. Of the total imported, 99% was duty-free fertilizer-grade peat. A duty of $0.25 per long ton was levied on poultry-and-stable-grade peat.

Foreign peat entered the United States through 26 customs districts in 1972, but 88% of the total was shipped through the Buffalo and Ogdensburg, N.Y.; Detroit, Mich.; Pembina, N. Dak.; St. Albans, Vt.; and Seattle, Wash., customs districts. The largest quantity, 85,000 tons, was shipped through the Ogdensburg district.

WORLD REVIEW

World production of peat in 1972 was estimated at 89 million short tons. While this appears to be less than one-half the quantity previously estimated for 1971 world output, it in actuality reflects a revision in the data previously reported for the U.S.S.R. Output statistics for the U.S.S.R. in 1972 and previous years were adjusted downward to reflect reported data based upon study tour reports and fully documented official production figures. The data now exclude peat produced by collective farms in the U.S.S.R., which had previously been estimated but for which no reliable data could be obtained.

Despite the exclusion of a portion of the total Soviet output, the U.S.S.R. was by far the largest peat producer with an estimated 89% of the world production. According to published Soviet figures, 30 million tons of peat was produced by State enterprises for agricultural use, and about 50 million tons was produced for fuel. Agricultural peat was used for general soil improvement and the manufacture of fertilizers, and fuel peat was used for generating electric power and for domestic and industrial heating.

Ireland ranked second in peat production with an estimated output of 5.8 million short tons. Virtually all of Ireland's production was fuel peat that was used for electric-power generating and household heating. A small amount of agricultural peat was produced, principally for export.

West Germany, the third-ranking peat

producer with 1.8 million short tons, provided about 2% of the world output. Most of the West German production was agricultural peat, but about one-fifth was consumed as fuel.

Other producers ranking in output in the order named were the United States, the Netherlands, Canada, and Finland. The combined output of these countries was, however, only 2% of the total. Although fourth in world production, output of the United States was only 0.7% of the world total.

[1] In addition to the countries listed, Austria Canada, Iceland, and Italy produce a negligible quantity of fuel peat. No data are available for East Germany, a major producer.

TECHNOLOGY

Experimental work conducted at the University of Sherbrooke, Quebec, Canada,[2] indicated that mercury present in waste water can be removed and recovered quantitatively by treatment with peat. The humic acids contained in peat are known to be good ion-exchange resins, and the studies have shown that contaminated waters can be made virtually mercury-free if treated with moss peat in the presence of a precipitating agent such as sodium sulfide. Recovery of mercury is accomplished by burning the peat containing mercury in the presence of a limited amount of air. Vapors of mercury and sulfur dioxide are eliminated in a scrubbing tower containing limestone and elemental sulfur, and metallic mercury can be decanted from the water.

Field and laboratory studies conducted at the University of Minnesota[3] have shown that peat soil and various mixtures of sand, calcitic limestone, and peat can be used as filter media to remove significant amounts of phosphorus and organic materials from wastewaters. The treatment processes used in the experiments were physical and chemical as well as biological in nature, and the major emphasis was placed upon the removal of phosphorus, which has become a major pollutant in recent years. The studies also showed that various types of peat can be used in such filter systems and that the systems are not only efficient, but they can be operated at relatively high application rates.

Additional research work on peat at the University of Sherbrooke,[4] evaluated the use of peat as an absorbing agent for the removal of coloring matter from the effluent of a dye house at a textile plant. Many of the dyes used by the textile industry are nonbiodegradable, and their removal in an economic manner remains a problem. Adsorption of these dyes with activated carbon is one of the most promising of the processes proposed or used, but activated carbon is a relatively expensive material for this use. The study concluded that sphagnum peat moss of the blond type has good absorption capacity for basic dyes, but this capacity decreases for dyes that are acidic. Also, with an actual effluent from a dye house, competitive adsorption with other polluting material decreased the efficiency of peat moss in reducing the concentration of dyestuff.

Laboratory tests,[5] confirmed partly on a pilot and technical scale, in Raciborz, Poland, show that peat can be used effectively as a basic raw material to obtain a number of activated carbons with good physical, chemical, and adsorption properties. Such carbons may be produced, both by gas activation in which peat is treated with steam, carbon dioxide, or air at 700° to 1,000°C, or by chemical activation, based upon the impregnation of peat with chemical compounds. The chemical activation method uses chemicals such as zinc chloride or phosphoric acid to impregnate the peat, after which it is carbonized and activated at 600° to 700°C. Activated carbons with a high proportion of micropores are generally used for gas and vapor adsorption, carbons with medium-sized pores are used for catalytic and special applications, and macroporous carbons serve as decolorizing and medicinal agents. Peat has been used for the production of all of the aforementioned types of activated carbon as a replacement raw material for wood charcoal, which is more costly and, in Poland, becoming increasingly less available because of a timber deficit. Baltic-type peat from the Szczencin and Lebork regions of Poland, which is characteristically low in ash content, is especially amenable to activated carbon production.

Perlite

By Arthur C. Meisinger[1]

Record totals were established in 1972 for production and consumption of crude and expanded perlite in the United States and effectively reversed the overall decline that had hit the domestic perlite industry in 1971. Compared with 1971 production, the quantity of crude perlite mined increased 31% and the quantity and value of crude perlite sold or used each increased 26%. Although there were three fewer expanding plants in operation during 1972, the quantities of expanded perlite produced and sold or used exceeded those of 1971 by 10% and 9%, respectively. The value of expanded perlite sold or used also reached a record total of $25.35 million for an increase of 9% over that of 1971. New Mexico and Illinois continued to be the leading States in production of crude and expanded perlite, respectively.

Table 1.—Crude and expanded perlite produced and sold or used by producers in the United States

(Thousand short tons and thousand dollars)

Year	Crude perlite						Expanded perlite		
	Quantity mined	Sold		Used at own plant to make expanded material		Total quantity sold and used	Quantity produced	Sold or used	
		Quantity	Value	Quantity	Value			Quantity	Value
1968	558	202	1,975	226	2,246	428	339	336	15,265
1969	613	205	2,087	266	3,013	471	405	402	22,100
1970	607	176	2,056	280	2,848	456	420	416	24,972
1971	495	175	2,062	257	2,879	432	389	385	23,156
1972	649	224	2,540	321	3,691	545	427	421	25,350

DOMESTIC PRODUCTION

Crude perlite was produced by 12 companies at 13 mines in seven States in 1972 compared with 11 companies and 12 mines in six States in 1971. The quantity of crude perlite mined was a record 649,000 tons surpassing by 11,000 tons the previous high of 638,000 tons mined in 1967. New Mexico, with 87% of the U.S. crude perlite mined, continued to be the principal producing State. Other producing States, in descending order, were Arizona, California, Nevada, Colorado, Idaho, and Texas.

Crude perlite sold or used to make expanded materials set record totals in quantity and value in 1972. Producers sold or used 545,000 tons of crude perlite valued at $6,231,000 compared with the previous high of 471,000 tons and $5,100,000 in 1969.

Crude perlite was expanded at 84 plants in 30 States in 1972, and record quantities were established for expanded perlite produced and sold or used. The quantity of expanded perlite produced was 427,000 tons compared with the previous high of 420,000 in 1970. The quantity of expanded perlite sold or used in 1972 was 421,000 tons and exceeded the previous high of 416,000 in 1970 by 5,000 tons. The value of expanded perlite sold or used was $25.35 million compared with the previous record total of $24.97 million in 1970. Illinois continued to be the leader in production of expanded perlite and in the quantity sold or used. Other States with significant production of expanded perlite in 1972 included California, Colorado, Florida, Kentucky, Mississippi, New Jersey, Pennsylvania, and Texas.

[7] Data may not add to totals shown because of independent rounding.

CONSUMPTION AND USES

Consumption of expanded perlite in the United States reached a record level of 421,000 tons in 1972. The percent disposition by end use is shown in table 3. As in 1971, filter aid, plaster aggregate, concrete aggregate, and insulation board (included with "Other" uses) were the principal domestic uses of expanded perlite. Compared with that of 1971, consumption of expanded perlite in filter aids, plaster aggregate, and low-temperature insulation each increased 2% in 1972 while use of expanded perlite in concrete aggregate decreased 2%. Use of expanded perlite in horticultural aggregates was 3% in 1972—the same as in 1971. "Other uses" totaled 57% compared with 60% in 1971 and included primarily insulation board, fillers, formed products, and smaller amounts of paint additives, texturing granules, charcoal base, refractories, and miscellaneous agricultural products.

Table 3.—End use of expanded perlite

(Percent)

Use	1971	1972
Filter aid	14	16
Plaster aggregate	10	12
Concrete aggregate	10	8
Horticultural aggregates	3	3
Low temperature insulation	2	4
Masonry and cavity fill insulation	1	(1)
Fillers	(2)	(2)
Formed products	(2)	(2)
Other [3]	60	57

[1] Less than 1%.
[2] Included with "Other" to avoid disclosing individual company confidential data.
[3] Includes insulation board.

PRICES

Producers sold crushed, cleaned, and sized crude perlite to expanding plants at an average price of $11.34 per short ton in 1972, and the portion used by producers in their own expanding plants was valued at an average of $11.50 per ton. The weighted average of both categories was $11.44 per ton which was the same value as in 1971.

Expanded perlite sold or used, according to expanders, had an average value of $60.17 compared with $60.07 per ton in 1971. However, average values by States in 1972 ranged from $32 to $144 per ton.

WORLD REVIEW

Greece.—Although 1972 production data for perlite in Greece were not available, production in 1971 was slightly lower than in 1970. The quantity of crude perlite ore produced in 1971 was 177,000 tons compared with 185,800 tons in 1970. Processed perlite in 1971 amounted to 104,500 tons compared with 117,600 tons in 1970. The quantity of perlite exported by Greece in 1970 and 1971 averaged 15% of crude ore production and 95% of processed ore production, respectively.

Philippines.—The quantity of perlite produced from the Legaspi City deposit of Trinity Lodge Mining Corp. was only 480 tons in 1972—a slight increase from the 1971 production of 457 tons.

TECHNOLOGY

Grefco, Inc., a subsidiary of General Refractories Co., initiated installation of air pollution control systems at its perlite processing plant in No Agua, N. Mex., and storage facilities in Antonito, Colo., in 1972. The estimated $1 million project was to be completed by mid-1973.

Two product development research projects, sponsored by the Perlite Institute, New York, were completed during the year. One project involved the durability characteristics of perlite cement plasters (stucco). The other study, in two parts, was concerned with the physical properties of perlite insulating concrete with added diatomaceous earth and hydrated lime, and the effect of moisture migration for various vent boards used in roof deck construction.

Crude Petroleum and Petroleum Products

By James G. Kirby,[1] David A. Carleton,[2] and Betty M. Moore[3]

The total demand[4] for petroleum products in 1972 exceeded the 6-billion-barrel mark for the first time, increasing from the 1971 level by 437 million barrels or 7.8%.

The high level of industrial activity, colder-than-normal weather, and the substitution of fuel oils for short supplies of natural gas and low-sulfur coals all contributed to the unusually high increase in domestic product demand of 7.9%. Refined products exports were down slightly from the 1971 level.

Domestic production of crude oil and natural gas liquids was unable to keep pace with the increased demand, and imports were increased 21.1% and stocks were reduced by 85 million barrels.

The Department of the Interior was able to satisfy court orders that had canceled leasing of areas off the Louisiana coast in 1971, and lease sales were held in September and December 1972. At yearend the Alaskan pipeline continued to be delayed by court orders pending resolution of environmental concerns.

The increasing volume of natural gas liquids recovered from natural gas has made it desirable to present data on these liquids with crude oil data, as these liquids are blended with refinery products and are similar to materials recovered from refinery gases.

The Bureau of Mines uses crude-oil production data (including field condensate) compiled by State agencies for those States that compile the information. Where such data are not available, monthly questionnaires are sent to all pipeline companies operating within the State. Annual canvasses and State agencies also provide supplemental information on the value of crude petroleum at wells, and the number of producing wells.

Individual refineries reported monthly receipts, input, stocks, refinery production, and deliveries. Data on both product stocks at refineries and pipeline and bulk terminal stocks are collected. These data are also published monthly. Annually, sales of fuel oils, asphalt and road oils by uses, and refinery capacity are canvassed.

Demand by Product.—*Gasoline.*—The domestic demand for motor gasoline increased 6.3% in 1972 to 2,333,777,000 barrels. Emission control devices added to new car engines to meet Federal Government standards have caused a sharp decline in efficiency, accounting, in part, for the sharp increase in demand. The demand for aviation gasoline continued the downward trend in both the domestic and export markets. Domestic demand declined 7.1% in 1972 to 16,628,000 barrels, and exports declined 57.3% to 529,000 barrels.

Distillate Fuel Oil.—Domestic demand for distillate fuel oil in 1972 was 1,066,049,000 barrels, compared with

---

[1] Industry economist, Division of Fossil Fuels—Mineral Supply (retired).

[2] Petroleum specialist, Division of Fossil Fuels—Mineral Supply.

[3] Statistical assistant, Division of Fossil Fuels—Mineral Supply.

[4] Certain terms as used in this chapter are more or less unique to the petroleum industry. Principal terms and their meaning are—

Total demand.—A derived figure representing total new supply plus decreases or minus increases in reported stocks. Because there are substantial secondary and consumers' stocks that are not reported to the Bureau of Mines, this figure varies considerably from consumption.

Domestic demand.—Total demand less exports.

New supply of all oils.—The sum of crude oil production, plus production of natural gas liquids, plus benzol (coke-oven) used for motor fuel, hydrogen, and other hydrocarbons, plus imports of crude oil and other petroleum products.

Transfers.—Crude oil conveyed to fuel-oil stocks without processing, or reclassification of products from one product category to another.

All oils.—Crude petroleum, natural gas liquids, and their derivatives.

971,316,000 barrels in 1971. The increase of 9.8% was the highest on record for this fuel. Distillate fuel oil in most instances has a low sulfur content that is able to meet the various metropolitan area sulfur standards and thus entered markets formerly reserved for coal and residual fuel oil. Industrial and utility users of natural gas had to switch to distillate fuel oils in some areas of the country during the last quarter of 1972 because of tight natural gas supplies.

Residual Fuel Oil.—Residual fuel oil total demand increased at the rate of 230,000 barrels daily in 1972 to 937,707,000 barrels, and about 90% of the growth was in the electric utility market. While residual fuel oil lost some markets to distillate fuel oil, it picked up others from coal and natural gas. Imported residual fuel oil supplied 68.0% of demand requirements in 1972; 34.3% of this imported oil had a sulfur content of less than 0.5%, while only 18.9% of the 1971 imports had a low sulfur content.

Kerosine.—Markets for kerosine continued to decline, and demand was down 5.7% in 1972. The total demand for the year was 85,943,000 barrels for uses other than jet fuel.

Jet Fuels.—The total demand for kerosine-type jet fuels increased 7.2% in 1972 to 294,041,000 barrels, but demand for the naphtha type declined 6.9% to 89,406,000 barrels. The military used 105,153,000 barrels of jet fuel in 1972, compared with 112,968,000 barrels in 1971.

Liquefied Gases and Ethane.—After 2 years of low growth, the demand for liquefied gases increased 12.4% in 1972 to 425,118,000 barrels. During the fourth quarter of the year, demand increased 14.0%. Excessive rains and cold weather in the midwest delayed crop harvests, and large amounts of propane were required to dry the grains for storage, in substitute for

natural gas which was in short supply. The demand for ethane increased 21.0% in 1972 to 106,201,000 barrels. More detail on liquefied gases and ethane can be found in the "Natural Gas Liquids" chapter.

Other Products.—This category includes refinery gas (still gas) used for fuel, asphalt, petrochemical feedstocks, petroleum coke, lubricating oils, special naphthas, miscellaneous products, road oil, and wax. Refiners used 170,993,000 barrels of still gas for fuel in 1972 and 14,678,000 barrels for petrochemical feedstocks. The domestic demand for asphalt increased 3.3% to 163,788,000 barrels (29,779,000 short tons). The demand for petrochemical feedstocks was strong in the domestic market, but exports declined. Domestic demand for the year increased 12.1% to 123,867,000 barrels, and exports decreased 15.3% to 4,457,000 barrels. Sales of marketable coke increased 10.5% in 1972. Exports increased 14.8% to 6,215,000 short tons, and domestic sales increased 7.0% to 7,074 million short tons. Domestic demand for petroleum coke, including 10,590,000 short tons of catalyst coke, was 17,664,000 short tons in 1972, an increase of 10.5%. The demand for lubricating oils increased 4.1% in 1972, but exports declined 6.0%. Domestic demand was 67,796,000 barrels, and exports comprised 14,935,000 barrels.

The total demand for special naphthas increased 7.0% in 1972 to 33,375,000 barrels. Domestic demand was 31,888,000 barrels and exports, 1,487,000 barrels. The domestic demand for road oil continued to decline in 1972. Demand was 7,538,000 barrels, down 11.2% from 1971. The domestic demand for petroleum wax increased 3.1% to 5,410,000 barrels, but exports declined 32.0% to 1,129,000 barrels. In addition to the above products refineries produced in small quantities a variety of products (petrolatum, medicinal oils, rust preventives, spray oils, etc.) which the Bureau of Mines grouped together as miscellaneous products. The domestic demand for these products in 1972 was 15,280,000 barrels, and exports were 1,062,000 barrels.

Shipments to U.S. Territories, Possessions, and Free Trade Zones.—Domestic demand, as defined in this chapter, refers to demand in all States of the United States. Shipments from the United States to territories, possessions, and free trade zones are included with exports. Any foreign receipts into these areas are not included in total imports shown.

Shipments from territories, possessions, or free trade zones to foreign countries are excluded from exports. Shipments from these areas into any State of the United States are included in import data.

Districts.—The Bureau of Mines reports production of crude petroleum and natural gas liquids and the number of wells drilled by States. Data for Louisiana, New Mexico, and Texas are also reported by districts.

New Mexico has two widely separated producing areas. The Southeastern district comprises mainly Lea, Eddy, Chaves, and Roosevelt Counties. The Northwestern district comprises mainly San Juan, Rio Arriba, Sandoval, and McKinley Counties.

Bureau of Mines producing districts in Texas correspond, with one exception, to the following grouping of the Texas Railroad Commission districts:

Bureau of Mines districts	*Railroad Commission districts*
Gulf Coast	Nos. 2 and 3.
West Texas	Nos. 7C, 8, and 8A.
East Proper	Part of No. 6 (East Texas field in Cherokee, Smith, Upshur, Rush, and Gregg).
Panhandle	No. 10.
Rest of State:	
North	Nos. 7B and 9.
Central	No. 1.
South	No. 4.
Other East Texas	Nos. 5 and 6 (exclusive of East Proper).

Separate production data are shown for the Louisiana Gulf Coast, including the offshore area.

Refinery operations are grouped by the Bureau of Mines into another set of districts called refining districts. These refining districts correspond with the grouping originated by the Petroleum Administration for War during World War II and called PAW districts (later changed to PAD districts).

PAD district	*Refining districts*
I	*East Coast*—District of Columbia and Maine, New Hampshire, Vermont, Massachusetts, Rhode Island, Connecticut, New Jersey, Delaware, Maryland, Virginia, North Carolina, South Carolina, Georgia, and Florida, and the following counties of New York: Cayuga, Tompkins, Chemung, and all counties east and north thereof; and the following counties of Pennsylvania: Bradford, Sullivan, Columbia, Montour, Northumberland, Dauphin, York, and all counties east thereof.
I	*Appalachian No. 1*—West Virginia and those parts of Pennsylvania and New York not included in the East Coast district.

II—*Appalachian No. 2*—The following counties of Ohio: Erie, Huron, Crawford, Marion, Delaware, Franklin, Pickaway, Ross, Pike, Scioto, and all counties east thereof.

II—*Indiana-Illinois-Kentucky*—Indiana, Illinois, Kentucky, Tennessee, Michigan, and that part of Ohio not included in the Appalachian district.

II—*Oklahoma-Kansas-Missouri*—Oklahoma, Kansas, Missouri, Nebraska, and Iowa.

II—*Minnesota-Wisconsin-North Dakota-South Dakota*—Minnesota, Wisconsin, North Dakota, and South Dakota.

III—*Texas Inland*—Texas, except Texas Gulf Coast district.

III—*Texas Gulf Coast*—The following counties of Texas: Newton, Orange, Jefferson, Jasper, Tyler, Hardin, Liberty, Chambers, Polk, San Jacinto, Montgomery, Harris, Galveston, Waller, Fort Bend, Brazoria, Wharton, Matagorda, Jackson, Victoria, Calhoun, Refugio, Aransas, San Patricio, Nueces, Kleberg, Kenedy, Willacy, and Cameron.

III—*Louisiana Gulf Coast*—The following parishes of Louisiana: Vernon, Rapides, Avoyelles, Pointe Coupee, West Feliciana, East Feliciana, Tangipahoa, St. Helena, Washington, and all parishes south thereof; the following counties of Mississippi: Pearl River, Stone, George, Hancock, Harrison, and Jackson; and Mobile and Baldwin Counties, Ala.

III—*North Louisiana-Arkansas*—Arkansas and those parts of Louisiana, Mississippi, and

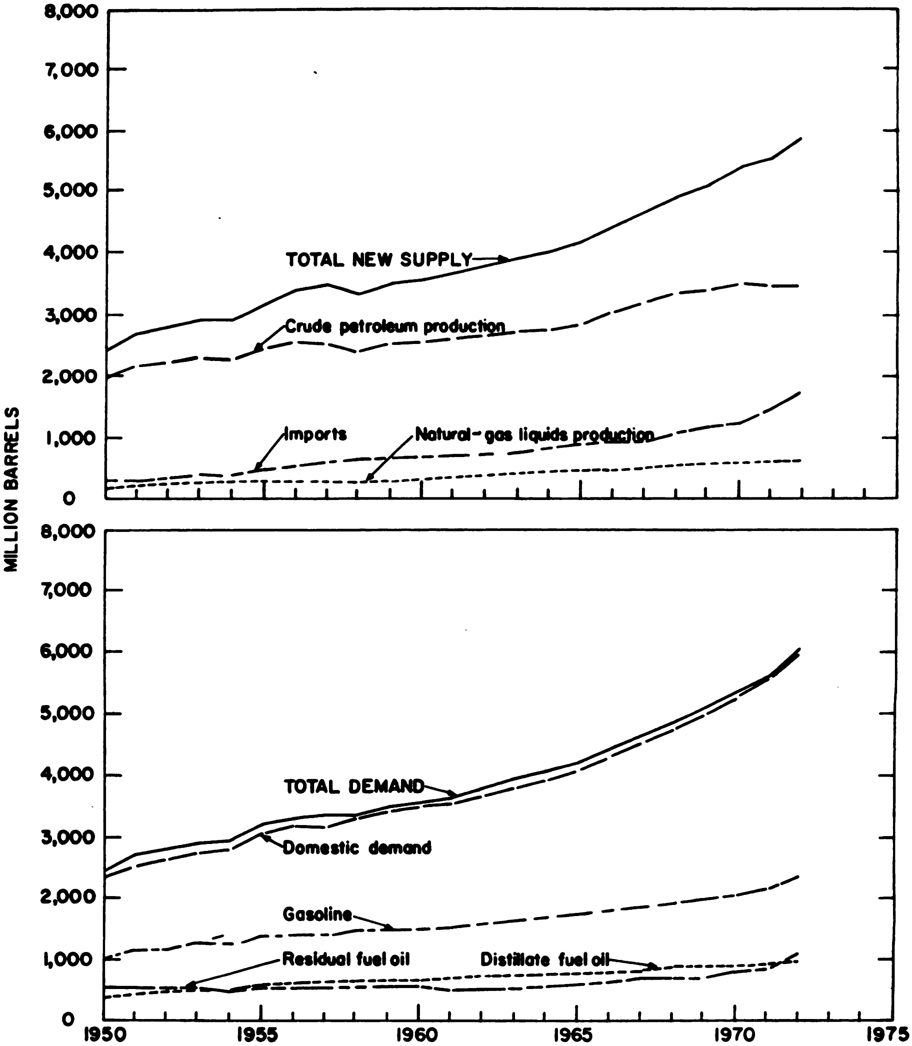

Figure 1.—Supply and demand of all oils in the United States.

Alabama not included in the Louisiana Gulf Coast district.

III—*New Mexico*—New Mexico.

IV—*Rocky Mountain*—Montana, Idaho, Wyoming, Utah, and Colorado.

V—*West Coast*—Washington, Oregon, California, Nevada, Alaska, Arizona, and Hawaii.

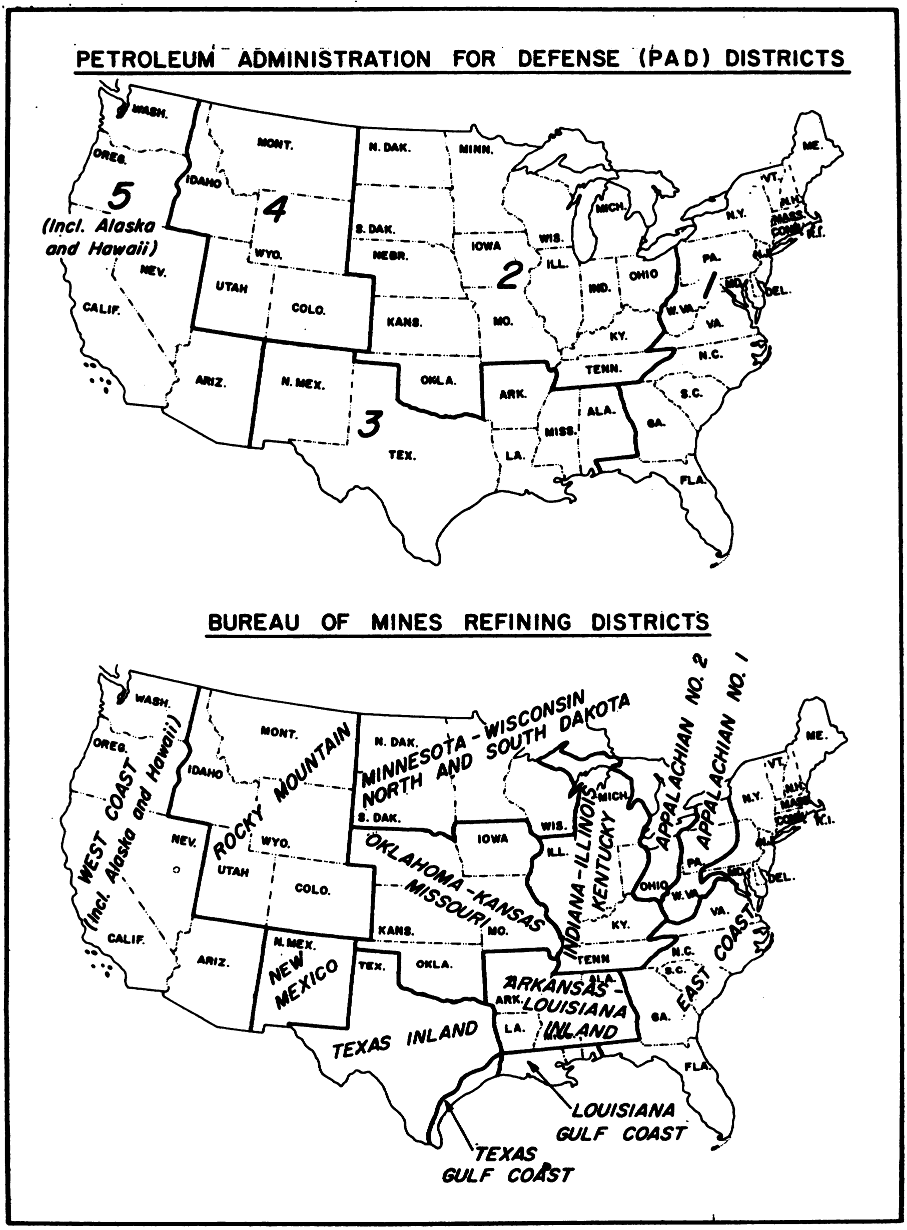

Figure 2.—Map of PAD Districts and Bureau of Mines Refining Districts.

CRUDE PETROLEUM

PRODUCTION

The production of crude oil (including lease condensate) in 1972 was 3,455,368,000 barrels, or a daily average producing rate of 9,441,000 barrels. For 1971, production was 3,453,914,000 barrels with a daily production average for the year of 9,463,000 barrels.

During the year, a tight supply situation developed, and several States with prorationing relaxed allowable rates in an effort to increase supply. Production in Texas for the year averaged 3,556,000 barrels daily compared with 3,350,000 barrels in 1971. As separation and desulfurization equipment was installed at new fields in northern Florida during the year, production increased from an average of 17,000 barrels per day in January to 83,000 barrels daily in December, and the daily average for the year was 46,000 barrels per day compared with 15,000 barrels in 1971. Production for the year increased at the rate of 12,000 barrels per day in Colorado, 6,000 in Alabama, 8,000 in Utah, and 3,000 in Michigan.

Production in 1972 declined at an average daily rate of 126,000 barrels in Louisiana, 34,000 in California, 23,000 in Wyoming, 17,000 in Oklahoma, 14,000 in Kansas, and 12,000 in Illinois.

CONSUMPTION

The total demand for crude oil in the United States in 1972 was 4,279,756,000 barrels, of which 3,472,432,000 was supplied from domestic sources, and 807,324,000 barrels came from foreign sources. The demand for domestic crude was down slightly from 1971, but the demand for foreign crude oil increased 33.0%.

Runs to Stills.—Refineries processed crude oil at an average daily rate of 11,696,000 barrels in 1972 and reached the highest daily level of operation in September when runs to stills averaged 12,113,000 barrels. Based on the total operable January 1, 1972, capacity, refineries operated at 88.0% of capacity in 1972.

Demand by State of Origin.—Distribution of domestic crude oil can be analyzed from the individual refinery reports which show origin of the crude oil receipts and from crude oil stock reports filed by refiners, pipeline companies, and terminal operators which show stocks of crude oil by States of origin and location. When long-distance shipments are involved, various crude oils may be mixed in transit or storage, and identification by origin may be only approximate.

SUPPLY AND DISTRIBUTION

The total distribution of crude oil in 1972 was 4,290.0 million barrels of which domestic crude oil accounted for 3,482.7 million barrels and foreign crude oil, 807.3 million barrels. The new supply of crude oil included 3,459.0 million barrels of crude oil and lease condensate produced in this country and 811.1 million barrels imported from foreign sources. Stocks of domestic crude oil declined 17.1 million barrels during 1972, but stocks of foreign crude oil increased 3.8 million barrels. The difference between supply and distribution, 10.2 million barrels, was classified as "unaccounted for" to avoid making arbitrary adjustments in the reported supply and consumption.

PRODUCTIVE CAPACITY

According to the American Petroleum Institute (API) the maximum crude oil production that could be attained in the United States as of January 1, 1973, was 10.3 million barrels daily, down 0.4 million barrels daily since January 1, 1972. This estimate was based on the assumption that such production could be achieved in 90 days with existing wells, well equipment, and present surface facilities, plus work changes that could be accomplished within that time. No production capacity was credited to the crude oil on the North Slope of Alaska since there was no way to market the oil, and installation of production equipment was incomplete.

WELLS

Drilling activity in 1972 increased for the first time since 1969 with 27,291 wells drilled, 1,440 more than in 1971. The drilling resulted in 11,306 new oil wells, 4,928 new gas wells, and 11,057 dry holes. The average depth of the wells drilled in 1972 was 4,932 feet, 126 feet deeper than the average in 1971.

States reporting the largest increase in drilling activity for the year were Texas with an increase of 395 wells drilled, Montana with 326, Pennsylvania with 260, New Mexico with 218, and Ohio with 174. In California, 410 fewer wells were drilled than in 1971.

Two lease sales were held by the Department of the Interior in 1972 for acreage off the Louisiana Gulf Coast, one in September and the other in December.

There were 508,443 oil wells producing at the end of 1972 compared with 517,318 on December 31, 1971.

RESERVES

The API Committee on Petroleum Reserves estimated reserves of crude oil as of December 31, 1972, to be 36,339 million barrels, a decline of 1,724 million barrels for the year. Only Florida, Michigan, Montana, and Utah reported additions to reserves during the year. Reserves declined 879 million barrels in Texas, 370 million barrels in Louisiana, 152 million barrels in California, and 102 million barrels in Oklahoma.

REFINED PRODUCTS

At yearend 1972, transportation bottlenecks occurred in some areas because of the inability of domestic crude oil production and refining capacity to keep pace with unprecedented demand. Little refinery expansion occurred in 1972. In addition, imports of foreign sweet crude oil and finished products were limited because of in-

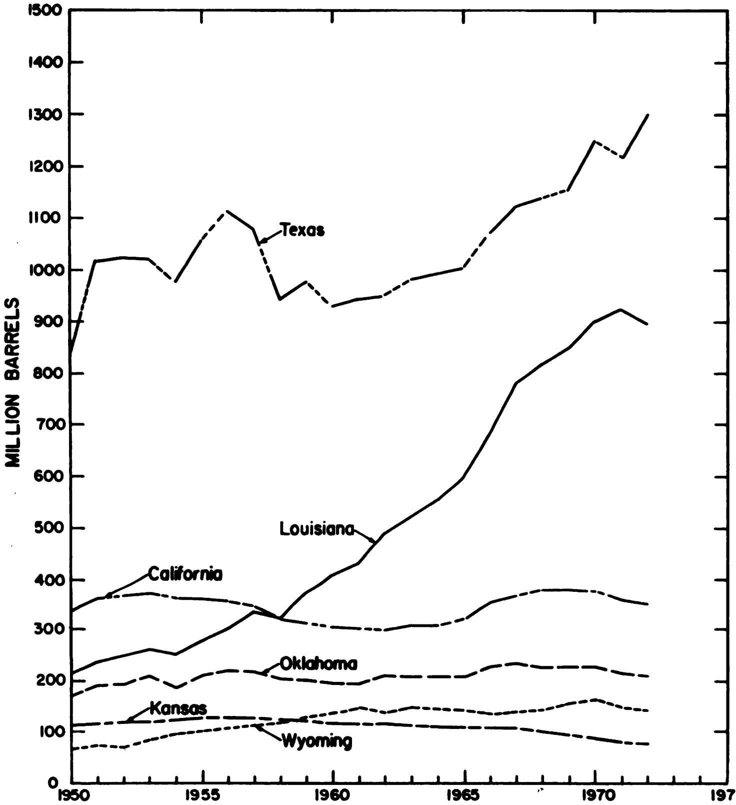

Figure 3.—Production of crude petroleum in the United States, by principal producing States.

creasing worldwide competition for quality fuels, and the United States lacked adequate dock and terminal facilities to handle expanded imports. Several inland refiners, especially those limited to refining sweet crude oil, had difficulty obtaining supplies and had to cutback on refinery operations. Higher cost of foreign crude oil, as a result of negotiations by the foreign governments and the devaluation of the dollar, eliminated much of the trading value of import tickets between inland and coastal refiners.

Gasoline was consumed principally in highway transport, aviation, mechanized farming, and power boating. Kerosine (other than the straight-run kerosine used as fuel in commercial jet aircraft) was used primarily in space heaters, as range oil, or for farm equipment. Distillate fuel oils, which include the light diesel fuels, were consumed for space heating, locomotive fuel, industrial use, electric utility use, vessel use, and military uses. Residual fuel oil was used primarily in electric utilities and for heavy-fuel use. Residual fuel is not normally moved by pipeline; its distribution depends on low-cost water transportation and limited tank movement.

Liquefied gases, in competition with kerosine and light distillate fuel oil for domestic use, were used as fuel in internal-combustion engines and were becoming increasingly important as the initial raw material in the development of many petrochemicals.

The total demand for petroleum products averaged 16,589,000 barrels per day in 1972, including a domestic demand of 16,367,000 barrels per day and exports of 222,000 barrels per day. Compared with 1971, total demand increased 7.8%, domestic demand increased 7.9%, and exports remained at the same level.

Total supply for the year averaged 16,370,000 barrels daily, and after allowing for crude oil losses and exports there was a decline in stocks in all oils averaging 232,000 barrels daily for the year.

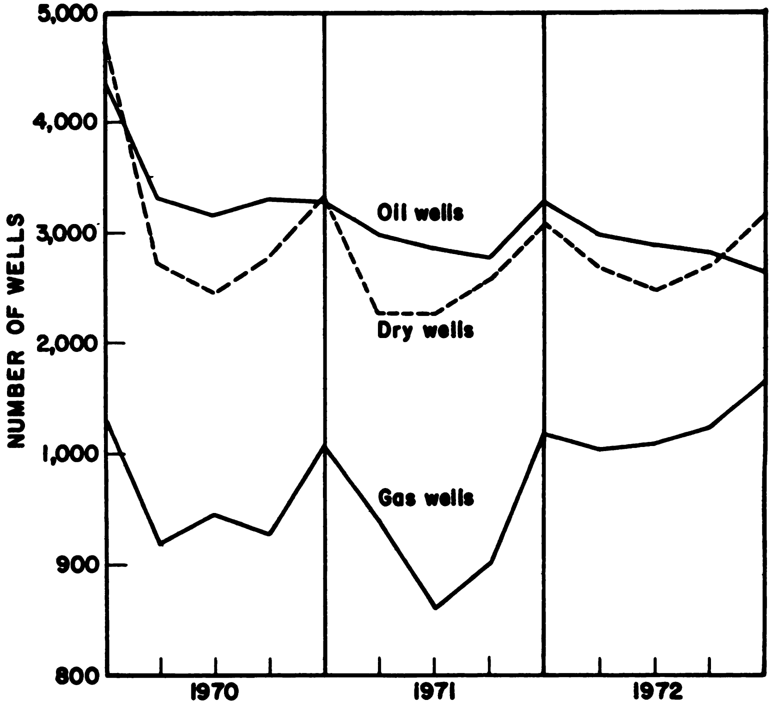

Figure 4.—Wells drilled for oil and gas in the United States, by quarters.

GASOLINE

The domestic demand for motor gasoline increased 6.3% in 1972 to 2,333,777,000 barrels, the highest increase reported since 1968. The high level of the general economy, which boosted new car sales to record levels, and the reduced efficiency of new car engines because of federal air emission standards and other equipment sent demand soaring. To keep up with the heavy demand, refineries maintained high yields of gasoline much later in the season than normal and entered the winter heating season with low stocks of distillate fuel oils which created spot shortages in some areas.

The new supply of motor gasoline in 1972 was 2,328 million barrels of which 1,986 million barrels was produced from crude oil, 307 million barrels from natural gas liquids, and 10 million barrels from other hydrocarbons and hydrogen; 25 million barrels was imported.

According to data compiled by API based on tax data reported by the States, 2,387 million barrels of motor gasoline was consumed in the United States in 1972 compared with 2,236 million in 1971. This differs from the demand data compiled by the Bureau of Mines, which do not include changes in secondary storage.

Aviation gasoline demand continued to decline in 1972 as it has for the past 14 years, and domestic demand was 16,628,000 barrels compared with 17,892,000 barrels in 1971.

KEROSINE

The markets for kerosine continued to decline in 1972, and demand was off 5.7%. Domestic demand was 85,854,000 barrels compared with 90,917,000 in 1971. The primary use for kerosine was for space heating, which represents about 78% of demand, but it is being replaced by more convenient fuels such as bottled gas (propane) and electricity.

DISTILLATE FUEL OIL

The 9.8% gain in domestic demand for distillate fuel oil in 1972 was attributed to colder-than-normal weather, the high level of industrial activity, and substitution for other fuels in areas where air quality restrictions limit the use of fuels with higher sulfur content, and where natural gas was in short supply. Domestic demand for the year was 1,066,049,000 barrels compared with 971,316,000 barrels in 1971. Exports declined from 2,761,000 barrels in 1971 to 1,214,000 barrels.

Meeting the strong demand for both gasoline and distillate fuel oil created problems for refiners in 1972. Some inland refiners had difficulty obtaining particular types of crude oil suited to their refineries and in some cases had to limit crude runs. The changeover from high yields of gasoline to distillate fuel oil was delayed until late fall, and stocks at the beginning of the 1972–73 heating season were uncomfortably low. Fortunately, the exceptionally cold weather of October and November did not continue. Controls were relaxed to permit more imports and refiners concentrated on higher production of distillate fuel oil, so that except for a few spot shortages in some areas, demand was met for the 1972–73 season.

The new supply of distillate fuel oil in 1972 was 1,030,960,000 barrels, an increase of 6.3% or 61,532,000 barrels more than in 1971. To meet the total demand requirements, 36,303,000 barrels were withdrawn from stocks.

RESIDUAL FUEL OIL

Residual fuel oil demand lost out in some heating and industrial markets because of air quality regulations, but the gain in the electric utility market was so high that the overall increase in the domestic demand for residual increased 10.5%. A strong factor in the growth was the increase in the new supply of low-sulfur residual fuel oil from domestic and foreign sources. About 34% of the residual fuel oil imported (exclusive of fuel for bunkering) had a sulfur content of 0.5% or less, while only 19% of the 1971 imports had this low a sulfur content. Over 22% of the residual produced in U.S. refineries in 1972 had a sulfur content of 0.5% or less, compared with 18% in 1971.

Electric utilities used 493,927,000 barrels for the generation of electric power in 1972 compared with 362,022,000 barrels in 1971.

The total demand for residual fuel oil in 1972 was 937,707,000 barrels including a domestic demand of 925,647,000 and exports of 12,060,000 barrels. The new supply for the year totaled 933,242,000 barrels of which 68.3% was imported. To meet demand, 4.5 million barrels were withdrawn from stocks.

JET FUELS

Jet fuel demand increased 3.6% in 1972, slightly below the 1971 increase of 3.9% and well below the 13% annual growth rate of the 1960's. Airline efforts to curtail some flights and establish a greater utilization of existing seating capacity was instrumental in limiting demand growth. In addition, military use was down. The demand for kerosine-type jet fuel increased 52,000 barrels per day during 1972 to 803,000 barrels. Demand for the naphtha-type jet, used primarily by the military, after having increased only slightly in 1971, continued its overall decline by falling to 244,000 barrels per day in 1972.

Imports of jet fuel averaged 194,000 barrels per day in 1972 of which 164,000 barrels was imported in bond for use as fuel for aircraft engaged in flights with destinations outside the United States. There is no custom duty on these imports, and bonded imports of such fuels were not subject to import control regulations.

LUBRICANTS

The total demand for lubricants in 1972 increased 4.1% to 67,796,000 barrels. The

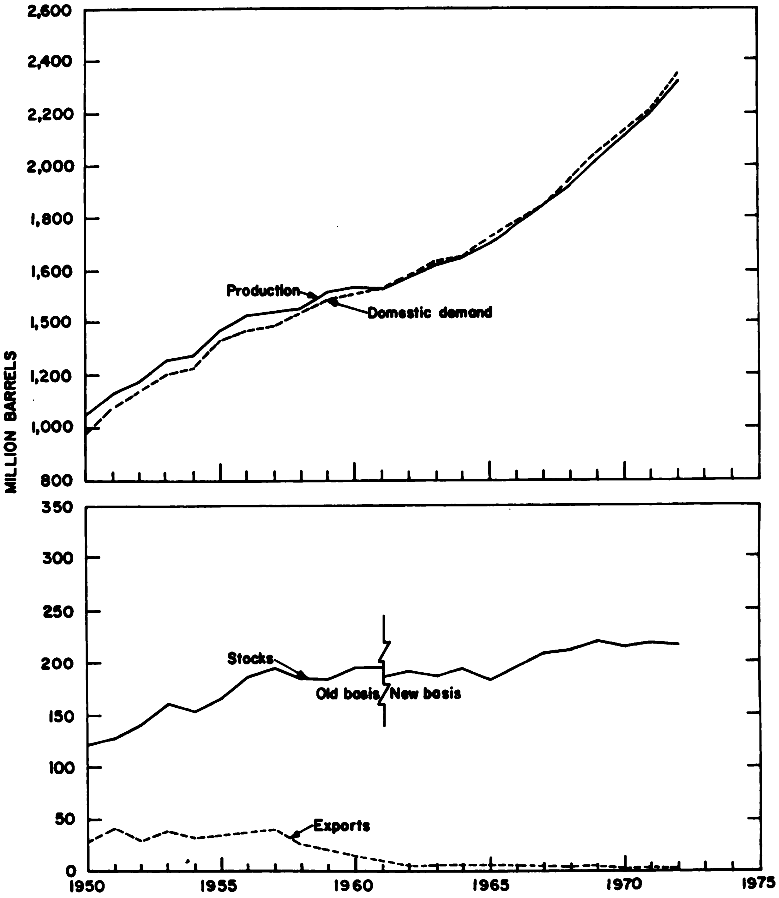

Figure 5.—Production, domestic demand, stocks, and exports of gasoline in the United States.

gain for the year was all in the domestic market, which was 52,801,000 barrels compared with 49,321,000 in 1971. Over half of the domestic sales of lubricants were for industrial use and the demand reacted to the level of industrial activity, which was up sharply in 1972.

LIQUEFIED GASES, ETHANE, AND ETHYLENE

Liquefied gases are derived from two sources. Those produced at refineries are called liquefied refinery gases to distinguish them from liquefied petroleum gases produced from natural gas. The liquefied petroleum gases (LPG) are all saturated (propane, butane, etc.). The liquefied refinery gases (LRG) may contain unsaturated compounds or olefins (propylene, butylene, etc.). The olefins are used as feedstocks for chemical plants. The saturated gases may be used as chemical raw materials or as fuel.

Separate data were collected on liquefied refinery gas used as fuel and that used as raw material for petrochemical feedstocks. Liquefied gases were also used in producing gasoline and are reported in this chapter as natural gas liquids at refineries or as gasoline.

Total demand for liquefied gases, excluding that blended into other products at refineries or terminals in 1972 was 425,118,000 barrels compared with 378,398,000 barrels in 1971. Domestic demand for the year increased 12.1%, and exports increased 22.1%. Through the first 9 months of 1972, domestic demand showed a significant gain over that of the same period of 1971, and in the last quarter it soared to 18.3%. Wet weather in the midwest farm belt delayed the crop harvest. Normally grain elevators use natural gas to dry the grain, but exceptionally cold weather caused a shortage of natural gas so that it was necessary to substitute liquefied gases to dry the grain.

The demand for ethane (including ethylene) was 106,201,000 barrels in 1972 compared with 87,744,000 barrels in 1971.

ASPHALT AND ROAD OIL

Shipments of asphalt and asphaltic products in the United States in 1972 were 31,121,000 short tons compared with 30,023,000 short tons in 1971. Asphalt for paving, which represents 77.4% of the total sales, was 24,100,000 short tons, up slightly from the 23,821,000 short tons sold in 1971. Shipments of roofing products increased a significant 20.3% in 1972 to 5,248,000 short tons, while shipments for all other products declined 3.6%. The shipment data include, in addition to refinery production and imports, various emulsifiers and blenders.

The domestic demand for asphalt in 1972 was 29,779,000 short tons, an increase for the year of 3.3%.

The demand for road oil decreased from 8,487,000 barrels in 1971 to 7,538,000 barrels in 1972.

OTHER PRODUCTS

Special Naphtha.—Special naphthas were used primarily for paint thinners, cleaning agents, and solvents. The domestic demand for special naphthas increased 7.1% in 1972 to 31,888,000 barrels, while exports increased 2.2% to 1,487,000 barrels.

Waxes.—The domestic demand for petroleum wax increased 3.1% in 1972 to 757,400 short tons, but exports declined 74,340 tons to 158,060 short tons so total demand for the year was off 5.3%. The annual survey of wax sales conducted by the API for 1972 represents about 79% of the domestic demand reported by the Bureau of Mines. A breakdown of the 1972 data, by end use and percentage change, from 1971 is as follows: Paperboard containers, 122,905 tons, down 5.6% paper wrappers, 95,678 tons, up 2.2% corrugated paperboard, 78,163 tons, up 8.8% candles, molded novelties, and decorative items, 103,601 tons, up 20.7%, and all other uses, 196,702 tons, up 9.1%.

Coke.—Domestic demand for petroleum coke increased 10.5% in 1972 to 17,664,000 short tons, while exports increased 14.8% for the year to 6,215,000 short tons; the result was that total demand was up a significant 11.6%. Refineries used 11,231,000 short tons as fuel in 1972, including 11,064,000 short tons of catalyst coke and 167,000 short tons of marketable coke. Catalyst coke is formed in the catalytic cracking units in the refining process and can only be used as a refinery fuel.

Still Gas.—Refineries used 1,046,492 million cubic feet of still gas as fuel in 1972, 6.6% more than in 1971. Still gas used as petrochemical feedstocks in 1972 totaled 14,678,000 barrels, 9.2% less than in 1971.

Petrochemical Feedstocks.—In addition to liquefied gases and ethane petroleum refineries supplied the United States petrochemical industry with 123,867,000 barrels of other feedstocks in 1972. This was an increase of 12.1% over the 1971 total. Exports declined 15.3% for the year to 4,457,000 barrels.

Unfinished Oils.—Unfinished oils are oils that have been partially refined and will be further processed by a refinery. The rerun (net) of unfinished oils represents the receipts of domestic or foreign oil plus or minus the stock change.

Miscellaneous Finished Products.—The petroleum industry produces a variety of miscellaneous products that are sold directly to consumers or in bulk to specialty companies which package and distribute them under various trade names. Included in this category would be absorption oils, medicinal oils, insecticides, petrochemicals and solvents. The domestic demand for these products in 1972 was 15,280,000 barrels.

TRANSPORTATION AND DISTRIBUTION

CRUDE OIL

A transportation system consisting of pipelines, tankers, barges, tank cars, and tank trucks moves the crude petroleum to refineries for processing. Refineries received 76.7% of their crude oil supply by pipeline, 22.1% by water, and the remaining 1.2% by tank cars and tank trucks in 1972.

States in PAD district I accounted for 39% of the petroleum product domestic demand in the United States. Refineries in this district supplied about 24% of the product demand. The supply of crude oil processed at these refineries in 1972 was 74% foreign; 22% was from other PAD districts, and 4% from within the district. PAD district II, the second largest consuming district, was also a deficit producing and refining area; however, output of refineries in that district represented 81% of demand in 1972. About 31% of the crude oil processed in refineries in PAD district II was produced in that district, 47% was received from PAD district III, and 8% was from PAD district IV; 14% was imported from foreign sources. Both PAD districts III and IV produced and refined petroleum in excess of their demand requirements and helped meet the supply deficits of other districts.

The refined products produced at refineries in PAD district V in 1972 represented almost 94% of the domestic product demand for that district. Crude oil produced in the district supplied 62% of refinery input, and foreign crude oil, 36%; 2% was received from other PAD districts.

Data collected on receipts of domestic and foreign crude petroleum at refineries in the United States show receipts from local production (intrastate), receipts from other States (interstate), and receipts of imported crude. These data by method of transportation indicate the final receipts by water, pipeline, and tank car and truck. Receipts of domestic crude by water usually are moved by pipeline from the point of production to the point of water shipment.

Total receipts of crude oil at refineries in 1972 were 4,279.2 million barrels, an increase of 198.4 million barrels for the year. Receipts from domestic sources increased 3.0 million barrels in 1972, overland receipts of foreign crude oil (from Canada) were 46.8 million barrels higher, and foreign receipts from overseas sources increased 148.6 million barrels.

More overseas foreign crude oil entered the midwest and gulf coast refineries in 1972 because domestic crude oil was in short supply, and exchanging of foreign quotas for domestic crude oil became more difficult.

Refineries processed 4,280.9 million barrels of crude oil in 1972, reported a net of 1.1 million barrels used for refinery fuel and losses, and withdrew 2.8 million barrels from stocks.

REFINED PRODUCTS

Domestic demand for petroleum products averaged 16,367,000 barrels daily in 1972, a record gain of 7.6% above the 15,213,000 barrels daily for 1971. The demand, broken down by PAD districts, is as follows: District I, 6,459,000; district II, 4,462,000; district III, 2,851,000; district IV, 436,000; and district V, 2,159,000.

PAD district I imported an average of

2,078,000 barrels daily of refined petroleum products in 1972 and received 2,926,000 barrels daily from other districts. Shipments from PAD district I to PAD district II averaged 141,000 barrels daily, and 21,000 barrels per day of petroleum products were exported.

PAD district II received an average of 759,000 barrels daily of refined products from other districts and imported 64,000. The district shipped 60,000 barrels daily to PAD district I and 73,000 barrels daily to PAD district III, and exported 10,000 barrels daily.

PAD district III shipped an average of 2,863,000 barrels daily of refined petroleum products to PAD district I, 594,000 barrels daily to PAD district II, 27,000 barrels daily to PAD district IV, and 63,000 barrels daily to PAD district V and exported 104,000 barrels daily. The district received 73,000 barrels per day of refined products from PAD district II and imported 45,000 barrels daily from foreign sources.

PAD district IV shipped an average of 105,000 barrels daily of refined petroleum products to other districts, received 53,000 barrels daily from other districts, and imported 15,000 barrels daily.

PAD district V received an average of 63,000 barrels daily of refined products from PAD district III and 81,000 barrels daily from PAD district IV, and imported 112,000 barrels daily. PAD district V shipped 3,000 barrels daily to PAD district I and 26,000 barrels daily to PAD district IV, and exported 87,000 barrels daily.

PIPELINES

As of January 1, 1971, there were 218,604 miles of pipelines transporting crude oil and refined products in the United States. This represents an increase of 9,126 miles from the total reported in the previous Bureau of Mines survey for January 1, 1968. The mileage of gathering lines declined 2,992 miles during the 3-year period; crude trunkline mileage increased 48,241 miles and 7,877 additional miles were reported for product pipelines.

Crude oil pipelines delivered 3,281.6 million barrels to refineries in 1972 compared with 3,094.9 million barrels in 1971. Petroleum products pipelines delivered 2,967.9 million barrels in 1972, an increase of 323.1 million barrels for the year.

The total crude oil required for pipeline fill as of January 1, 1971, was 73,642,000 barrels. Line fill for product pipelines required 39,908,000 barrels.

RAIL, TANK TRUCK, BARGE AND TANKERS

According to the annual study of the Association of Oil Pipelines, the total tonnage of crude petroleum and petroleum products transported in 1971 was 1,719,813,000 short tons of which 46.9% was moved by pipelines, 24.2% by water carriers, 27.4% by motor carriers, and 1.5% by railroads. Petroleum products represent 64.2% of the total volume transported, 43.0% of the pipeline movements, 72.5% of the water carrier movements, 91.3% of motor carrier movements, and 96.6% of the railroad movement.

STOCKS

Stocks of all oils at the end of 1972 totaled 959.0 million barrels, the lowest year-end level since 1967. The decline for the year was 85.0 million barrels, of which refined products stocks were down 65.8 million barrels and stocks of crude oil were down 13.2 million barrels. Of deep concern were stocks of distillate fuel oil which had declined 36.3 million barrels during 1972 and were at the lowest December closing level since 1966. Fortunately, because of warmer-than-normal weather during the first quarter of 1973, and the fact that refiners concentrated on a high distillate fuel oil output, serious shortages were averted in the 1972–73 heating season.

A tight crude oil supply situation developed in the last half of 1972 and some refiners had to cutback operations. By year-end, crude oil stocks declined to 246.4 million barrels, the lowest level since 1966.

PRICES

Crude Oil.—With the exception of a few changes in December for Pennsylvania-grade crude oil, there were no changes in posted prices in 1972. The average value of crude oil at the wellhead in 1972 was $3.39 per barrel, the same as in 1971.

Refined Products.—The price controls in effect in 1972 kept refinery prices at the August 1971 level through most of the year, and though there were some upward adjustments in distillates and lubricating oils late in 1972, average refinery prices were down slightly from 1971. Tanker rates were below the 1971 levels, and this was reflected in the decline in posted prices for the heavy fuel oils at the seaboard.

The average price of regular-grade gasoline at service stations, based on 55 representative U.S. cities, was down 0.7 cent per gallon in 1972, but State and local taxes increased 0.4 cent per gallon so the average price to the consumer declined only 0.3 cent for the year.

When price controls went into effect in August 1971 stocks were at a high level and product prices were low. Motor gasoline was still in the peak summer demand period when prices are normally higher, but for heating oil this was still within the months that discounts are used as an incentive to encourage summer fill-up of customers' storage facilities to ease peak winter demands. The low price base for distillates was cited as one of the reasons refiners delayed adjusting refinery production from gasoline to distillate fuel oil until later in the 1972 season.

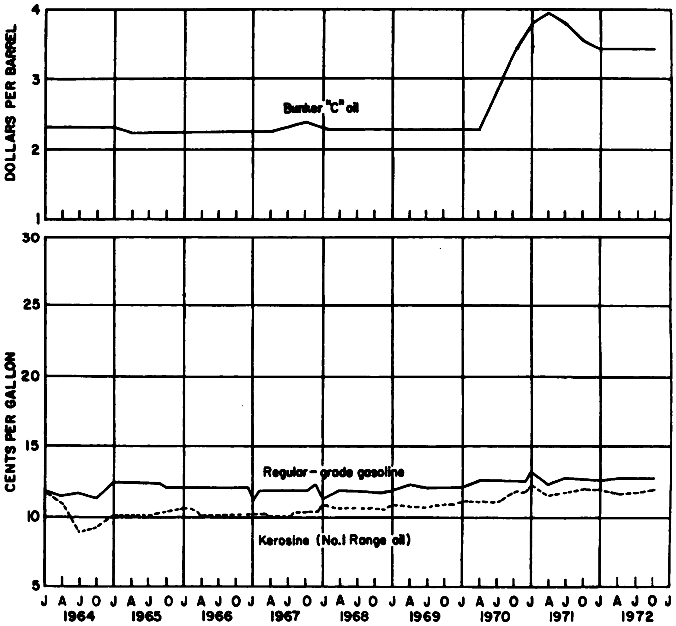

Figure 6.—Prices of Bunker "C" oil at New York Harbor, No. 1 Range oil at Chicago district, and regular-grade at refineries in Oklahoma, by quarters.

FOREIGN TRADE

Imports of crude oil and refined products totaled 1,735.3 million barrels in 1972 compared with 1,432.9 million in 1971. Crude oil accounted for 197.7 million barrels of the 302.4-million-barrel increase. About midyear it became apparent that domestic crude oil production could not be increased enough to meet demand requirements, and it was necessary to adjust import quotas upward.

Crude oil imports for the year were 811,135,000 barrels of which 38.5% was from Canada, 13.5% from other Western Hemisphere countries, 21.2% from Africa, 19.3% from the Middle East, and 7.5% from other Eastern Hemisphere countries.

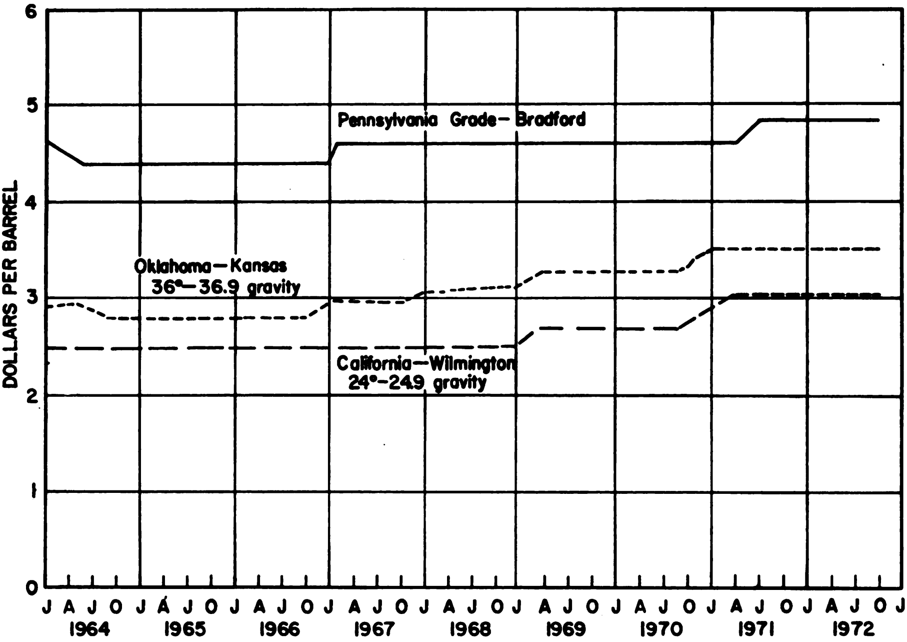

Figure 7.—Posted prices of selected grades of crude petroleum in the United States, by quarters.

Canada supplied 99.5% of the natural gasoline and condensate imported into this country in 1972, and other Western Hemisphere countries supplied the rest of the 31,428,000 barrels.

Unfinished oils imported for further refining in 1972 totaled 45,705,000 barrels, and these were primarily from South American and the Caribbean.

Refined product imports for the year were 846,988,000 barrels. Canada supplied 7.3%; other Western Hemisphere countries, 81.4%; Europe, 7.6%; Africa, 1.3%; the Middle East, 1.4%; and other Eastern Hemisphere countries, 1.0%. Included in the total refined petroleum product imports were 59,980,000 barrels of jet fuels, 5,296,000 barrels of distillate fuel oil, and 40,769,000 barrels of residual fuel oil which were withdrawn from bond for use as fuel for aircraft and vessels engaged in overseas commerce. These imports were exempted from oil import controls and from tariff duties. Residual fuel oil imported by the military for offshore use in 1972 totaled 5,035,000 barrels. This use by the military was exempt from import control regulations, but other imports by the military were under quota or license.

Exports of petroleum in 1972 were 81,468,000 barrels which was slightly below the 1971 level. There was a strong export market for petroleum coke and liquefied gases which offset much of the declines for the other products.

The international tanker market in 1972, though less volatile than in 1971, reflected worldwide marketing conditions. Freight rates continued the decline which near the end of 1970 had reached the lowest level since early 1967. By midspring the single-voyage (spot) tanker market, according to a London-based chartering service, flatten-out at about Worldscale 55, almost 100 Worldscale points below the spring 1971 level. Worldwide demand for oil was still below its normal growth rate, and the second mild winter left petroleum marketers overstocked with crude. Some relief came in mid-1972 shortly following a 3-month strike by Japanese seamen and the interruption of crude oil production by the nationalization of most Iraq Petroleum Co., Ltd., holdings in Iraq. The upturn continued through the remainder of 1972 as world demand was up and the United States became more dependent on imports. At yearend spot market rates were about 12.5% Worldscale.

NATIVE ASPHALT

Bituminous Limestone, Sandstone, and Gilsonite.—Natural rock asphalt and limestone rock asphalt were produced in Alabama, Missouri, and Texas and were used for road building material. Gilsonite was produced in Utah, and most was shipped to a refinery in Colorado and converted into petroleum products. The total production of native asphalts and related bitumens in 1972 was 1,995,374 short tons with a value of $10,303,000.

WORLD REVIEW

During 1972 much of the petroleum consuming and producing world developed a growing awareness of an impending energy crisis. This was highlighted by fuel shortages in several marketing areas and associated supply and financial problems.

Price and ownership disputes and agreements continued to feature the confrontations between the major international oil companies and members of the Organization of the Petroleum Exporting Companies (OPEC). A major price adjustment early in the year reflected the devaluation of the U.S. dollar in 1971.

World crude oil production in 1972 increased 5.3% to a total of about 50.8 million barrels per day. This compares with a 5.7% increase in 1971. Production increases in the Eastern Hemisphere were lower than in the past because of certain restraints. Kuwait joined Libya in limiting production for conservation purposes. Output in Iraq was hindered by the nationalization of most of the country's production capacity. In addition major union strikes in Japan and Australia affected production in Abu Dhabi and other Middle East countries.

Exploration and development drilling increased after several years of decline. Most of the increase was in the United States where wells drilled increased 5.5%. Other areas of significant exploration were the Canadian Arctic, the northern parts of the North Sea, Saudi Arabia, Peru, Egypt's western desert, west-central Africa, offshore northwestern Australia, and Indonesia.

Algeria.—The Algerian state oil company Société Nationale pour la Recherche, la Production, la Transport, la Transformation, et la Commercialisation des Hydrocarbures (SONATRACH) was successful during the year in obtaining customers, including several foreign countries and the major international oil companies, for its nationalized oil production. Algeria nationalized essentially all of its production in 1971, and it was doubtful whether SONATRACH could market all of its output. Unique among the recent agreements was SONATRACH's long-term contract with Commonwealth Oil Refining Co. (Corco). The pioneering $8 billion, 25-year contract calls for the delivery to Corco of 380 million tons (about 2.9 billion barrels) of crude oil and other hydrocarbon materials.

Angola.—Crude oil shipments commenced from the new Cabeca da Cobra field located about 25 miles from the port of Santo Antonio do Zaire. Operated by a subsidiary of Petrofina, Inc., for a group of Belgian, Portuguese, and U.S. companies, the field started production from 10 wells at a rate of 1,800 barrels per day.

Argentina.—During the year the Government approved a $170 million expansion program for Yacimientos Petrolíferos Fiscales (YPF). The program included substantial increases in exploration, production, and refining. Crude oil production is to be raised to 550,000 barrels per day. Included in the program is further exploration and development on Tierra del Fuego and in the Santa Cruz-Condor area and refinery expansion in the Buenos Aires area.

Austria.—Attempts by the state company Österreichische Mineralölverwaltung, A. G. (ÖMv) to find new sources of oil was concentrated in drilling efforts abroad; however, the results were not promising. The well drilled in the Tunisia's Gulf of Hammamet was dry, but seismic surveys are scheduled for 1973. Other drilling resulted in the discovery of gas in Iran and Austria.

Bahamas.—A $35 million port and oil tanker terminal capable of handling up to 350,000-deadweight-ton tankers and over 400,000 barrels per day is scheduled for completion in 1974. The project is a joint venture of the Bahama Government and a private U.S. firm.

Expansion of the 250,000-barrel-per-day Freeport refinery will increase the capacity to 500,000 barrels per day. The plant, which is scheduled for completion in early 1973, will have a throughput capacity larger than any in the United States.

Bahrain.—A $90 million drydock for tankers of up to 300,000 deadweight tons, to be built by the Organization of Arab Petroleum Exporting Countries (OAPEC), is to be located in Bahrain. Cost of the project, which is to begin in 1973, will be shared 60% by OAPEC member states and 40% by Portuguese and Japanese companies.

Brazil.—Production was slightly below the 1971 level and the offshore Sergipe field was not expected to go into operation until mid-1973. Reportedly, the Guaricema and Caioba fields will produce about 60,000 barrels per day at that time and only the Atalaia producing platform needs to be completed.

Canada.—Whereas many natural gas discoveries have been reported in the Mackenzie Delta of northwestern Canada, the first oil discovery in the delta in 3 years was made in September 1972. Oil of 24° API gravity was encountered in several sands. Exploration in the Atlantic Ocean southwest of Sable Island resulted in a third gas find. Flow rates from five productive zones ranged from 5 to 21 million cubic feet per day and three zones tested 120 barrels per day of 46–48° API gravity condensate.

An agreement was signed in November 1972 between the provincial government of Nova Scotia and Shaheen Natural Resources for the construction of a 200,000-barrel-per-day refinery on the Strait of Canso to be completed in 1974–75. The plant will be the biggest in Canada, and Shaheen will be the country's third largest refiner. Completion of the agreement is subject to a firm, long-term supply contract and a satisfactory construction price. The complete project is estimated to cost $223 million. Shaheen's other refinery, the 100,000-barrel-per-day Come-by-Chance refinery, is due onstream in 1973. It was forecast by several large Canadian oil companies in testimony before the Alberta Energy Board that synthetic crude oil production from Alberta tar sands should reach 1.0 million barrels per day by 1985 and 3.5 million barrels per day by the end of the century.

China, People's Republic of.—Under a current 5-year trade agreement, Romania is to deliver 30 drilling rigs per year, each capable of reaching 16,400 feet, indicating the People's Republic of China's increasing interest in finding new reserves. Production of crude oil and shale oil in 1972 was about 30 million tons (600,000 barrels per day). In addition, the Chinese were preparing to drill offshore in the Gulf of Pohai where chances of finding oil are rated high. A four-legged, self-elevating drilling barge is to be delivered in March 1972 by a Japanese firm. A U.S. geologist estimated that the country's recoverable crude oil reserves in established oil-bearing areas at 19.6 billion barrels which, if fully developed, would allow a production of 2,700,000 barrels per day.

Columbia.—Production of crude oil was down considerably in 1972 because of conservation measures and dwindling reserves. An arbitration board determined that the Putumayo field was being overproduced, and the Government ordered the company to cut production from 70,000 to 30,000 barrels per day. Production from most other fields continued to decline, and no new discoveries seem likely to reverse the trend. The only new field discovery was in the Upper Magdalena area and tested less than 1,000 barrels per day.

Congo (Brazzaville).—In March, production from the offshore meraude Marine field started at an initial rate of 100,000 barrels per day and was expected to reach 500,000 barrels per day by 1974. The field was discovered in 1969 and has presented many problems because of its heavy crude oil. The only other field is the onshore Pointe Indienne oilfield, where production has declined from 14,000 barrels per day to less than 500 barrels per day.

Denmark.—Dan oilfield, Denmark's first, located 160 miles offshore in the North Sea started production on July 4. Initial production was about 8,000 barrels per day; however, the producing platform is capable of handling up to 30,000 barrels per day in case nearby geological structures prove to have commercial reserves. Production was tankered to coastal refineries. The producing company, Dansk Undergrunds Consortium (DUC), is required to deliver the main share of Dan production to Denmark. Later in the year DUC announced that it would attempt to stimulate the production capability of the oil-bearing chalk formation in the field, which was experiencing production difficulties. DUC also planned to drill five exploration wells, four of which would be offshore.

Ecuador.—During August the first shipment of crude oil from the Oriente region of Ecuador was delivered via a 318-mile pipeline to the deepwater terminal at Balao near the port of Esmeraldas. This marked the beginning of Ecuador's role as a major Latin American oil exporter. Exports averaged 200,000 barrels per day at yearend.

The Ministry of Natural Resources announced that the joint operations of Texaco Petroleum Co. and Ecuadorian Gulf Oil Co. had drilled 115 wells in their concession area in the Oriente region of Ecuador since they began exploration there 5 years ago and that 104 of these were producing wells. This group is Ecuador's major producer.

The latest in a series of regulation changes designed to tighten control of the Nation's oil industry occurred in 1972. Main items in the new rules include the relinquishment of 60% of each company's concession area within 12 months, a 15% surcharge on the f.o.b. value of crude oil exports, and the requirement that all companies operating in Ecuador renegotiate their contracts with the Government. In addition tax reference prices were introduced. Government income from oil exports is estimated now at $1.40 per barrel.

Egypt, Arab Republic of.—Production from existing fields (excluding those operated by Israel in occupied Sinai) continued to decline. This was due primarily to declining pressure at the country's largest oilfield, El Morgan field in the Gulf of Suez. However, production is expected to increase in the near future as a 300,000-barrel-per-day water injection project is being installed at El Morgan. It will be one of the world's largest waterflood pressure maintenance projects and will cost more than $30 million. A new field in the Western Desert came onstream during 1972 at a rate of 10,000 barrels per day, and two other Western Desert fields (one 20,000 barrels per day) were scheduled for production in early 1973.

The Government also offered a new invitation to foreign companies to explore for oil in the Arab Republic of Egypt. Agreements of the production-sharing or service-contract type with flexible terms are envisaged. A number of U.S. independent and large European companies have shown an interest.

France.—Exploration continued to be concentrated in the Aquitaine region. A total of 13 exploratory wells were drilled in 1972 compared to 12 in 1971, and geophysical activity decreased about 20%. French companies continued to explore for oil in foreign areas at a rapid pace. Regions of major activity include the North Sea, Africa, Canada, and Iran. French companies have also been seeking maritime permits on the Atlantic and Mediterranean Continental Shelves of France. Production of crude oil by French companies outside France averaged about 1.5 million barrels per day in 1972.

Gabon.—The Grondin-Marine field discovered 25 miles offshore in 1971 by Société Elf des Pétroles d'Afrique Equatoriale was scheduled to come into production in early 1973. Production is expected to average about 40,000 barrels per day.

Germany, West.—After many months of negotiation following the 1969 decision by the International Court of Justice in The Hague, which upheld West Germany's claim to the North Sea Continental Shelf, Denmark, the Netherlands, and West Germany agreed to new demarcation lines effective November 7, 1972. The new agreement increased the size of the West German Continental Shelf from about 14,700 square miles to about 21,800 square miles. Most of the newly acquired area, in addition to much of the uncontested West Germany Continental Shelf area, will be explored by the North Sea Consortium, a group comprised of both domestic and foreign companies.

Several companies, including United States, French, and West German interests, plan to construct 30 more caverns for underground storage of 70 million barrels of oil south of Emden to comply with future stockpiling requirements.

Greece.—The Government awarded licenses to two local entrepreneurs to build new refining facilities. One license was for expanding the throughput capacity at the existing refinery at Eleusis (near Athens) by 70,000 barrels per day. The unit is to be completed by 1974. The other license was for a new refinery to be built near Pachi near Megara, also in the Athens area. It will have a capacity of 70,000 barrels per day and is to be completed by the end of 1974. Under a unique arrangement, the Government has the right to 50% of net profits or, in the absence of adequate profit, to $0.40 per ton of crude oil refined.

Greenland.—Oil concession grants were further delayed, and drilling is not expected until 1974. However, the Danish Ministry for Greenland distributed a concession draft to interested concerns in October 1972, and licenses were expected to be issued in 1973. Interest centers on the offshore area west of Greenland, near the promising northeastern Canadian areas, and concessions are to be granted initially in the southern and central zones, up to the 72d parallel.

Guatemala.—After years of unsuccessful search, Guatemala's first discovery well was completed in 1972. The well was drilled in the La Tortugas Valley of Northeastern Guatemala by Recursos del Norte, a subsidiary of Basic Resources International of Canada. It flowed at a rate of 1,300 barrels per day. A second well flowed at 1,840 barrels per day. The company plans two more wells in 1973.

India.—A major policy shift took place in India which affected oil production and exploration. Because of the apparent failure of the Government-operated Oil and Gas Commission to find more oil, it became evident that the continued nearly complete reliance on Soviet technology had to be terminated. India is expected to grant offshore drilling contracts to Western companies covering an area of about 100,000 square miles. Production in 1972 averaged about 155,700 barrels per day, 9% above the 1971 level. The production was shared nearly equally between the States of Assam and Gujarat.

Indonesia.—Annual crude oil production in Indonesia exceeded 1 million barrels per day for the first time in 1972. At yearend production rates were approaching 1.2 million barrels per day. The increase came from two new offshore fields as well as from established onshore fields in Sumatra. Japan, the United States, and Trinidad took the bulk of the increased crude oil exports. It was announced in 1972 that since 1966, when Indonesia adopted the production-sharing contract system, output has doubled, more than $1 billion has been invested by foreign concerns, and about 40 contracts have been signed, mostly by U.S. companies, covering more than 3 million square miles on onshore and offshore areas, and that since 1968, 43 new oil and gas accumulations have been found.

The Petromer Trend group of companies found oil on the Vogelkop Peninsula of West Irian. The well flowed 43° API gravity, low-sulfur crude oil at a rate of 1,680 barrels per day. This was the first discovery in the Vogelkop area since 1954. In addition, initial production offshore Kalimantan (Indonesian Borneo) began in late 1972 when the Attaka oilfield came onstream. When fully developed by late 1973 it is expected to produce 100,000 barrels per day. Two other offshore fields were also producing off Java.

Iran.—In June, the Shah of Iran announced a new long-term relationship between the Government and the large international consortium that operates in Iran. Reportedly, the consortium would turn over the huge Abadan refinery to the National Iranian Oil Co. (NIOC) and in turn build a new refinery on Kharg Island. Also included was the transfer to NIOC of substantial amounts of crude for its own use of distribution. At yearend, a formal agreement covering the new relationship had not been reached.

The only discovery announced during 1972 was made by Bushehr Petroleum Co., owned jointly by Amerada Hess Corp. and NIOC. The discovery well tested at 2,000 to 3,000 barrels per day of 14° API gravity oil on a tract adjoining the Fereidoon field near the center of the Persian Gulf. Lavan Petroleum Co. placed in operation two 100,000-gallon-per-day seawater-desalting plants to improve crude oil recovery from its offshore Sassan field.

Completion of two tanker-loading berths increased the loading capacity at the Kharg Island terminal in November 1972 by 60,000 tons per hour (about 440,000 barrels per hour) and doubled the total capacity of the terminal. One of the new berths can accommodate tankers up to 500,000 deadweight tons and the other 300,000 deadweight tons. With the addition of three large tanks, storage capacity at Kharg Island totaled 14 million barrels.

Important projects undertaken were a 40,000-barrel-per-day refinery at Fars, a 20,000-barrel-per-day refinery on Lavan Island, expansion of the Kermanshah refinery by 15,000 barrels per day, and several large liquefied natural gas (LNG) projects involving Japanese and U.S. partners. In addition, NIOC announced that the capacity of the Tehran refinery would be increased by 100,000 barrels per day to 190,000 barrels per day at a cost of $100 million to meet the increasing demand of central and northern Iran.

Abroad, NIOC agreed to participate in the construction of refineries in Belgium and Greece and to supply crude oil to the 50,000-barrel-per-day refinery at Sasolburg in the Republic of South Africa.

Also, NIOC was to establish a 60,000-barrel-per-day refinery in the Philippines in which it will have a 50% interest and will also provide its crude oil requirements. NIOC already shares in the ownership of two other overseas refineries and has agreed to participate in another.

Iraq.—On June 1 the Iraqi Government nationalized the holdings of Iraq Petroleum Co. (IPC). The company is owned by British, Dutch, French, U.S. and other interests. The affiliates of IPC—Mosul Petroleum Co. Ltd. with a small amount of production in the north and Basrah Petroleum Co. with substantial production in the south—were not affected. Principal among the properties seized were the Kirkuk oilfield (1,117,000 barrels per day in 1971) and the pipelines to the Syrian border which carry crude oil to Mediterranean terminals. At the time of nationalization, the Government promised the French shareholder special terms.

Production from North Rumaila with technical assistance from the U.S.S.R. showed a sharp increase to about 100,000 barrels per day. In late 1972 Soviet officials and the Iraq National Oil Co. (INOC) were considering plans to increase the production to 360,000 barrels per day.

Iraq signed an important service contract agreement with Brazil's state-owned company, Petróleo Brasileiro, S.A. (PETROBRÁS) covering three exploratory blocks totaling 7,900 square kilometers. The agreement called for PETROBRÁS to provide technical and marketing expertise to INOC in return for production offtake privileges.

Ireland.—The U.S. firm Marathon Oil Co. holds leases on nearly three-fourths of Ireland's land area and extensive areas off the south and west coasts. A small number of dry wells have been drilled on land. In July an offshore well tested gas from two formations; however, the discovery failed to confirm a field of commercial size. At yearend Marathon was awaiting government approval to drill its fifth well in the Celtic Sea.

Israel.—Throughput of the Eilat-Ashqelon pipeline during 1972 reached 25.5 million tons (about 510,000 barrels per day), a 31% increase over the 19 million tons carried in 1971. The increase was made possible by the addition of two pump stations, increased storage capacity, and the installation of a fourth loading terminal at Ashqelon. Annual capacity of the line is now 30 million tons and as originally planned should eventually reach 60 million tons per year. Production from Heletz field in 1972 dropped 21% from 1971 to only 47,365 tons and is expected to stop entirely within a year or two. Production from Abu Rudeis and other oilfields on the Sinai Peninsula captured from the Arab Republic of Egypt was reported at 5.25 million tons (about 105,000 barrels per day) in 1972 and was expected to reach 6 million tons in 1973. Reportedly, as much as 3 million tons of Sinai crude oil was exported.

Recent press reports indicate that of the 30 million tons of crude expected to transit the Eilat-Ashqelon pipeline in 1973, about 6 million tons will be destined for use at the Haifa refinery and 1.5 million for the new Ashdod refinery which will begin operating in early 1973.

Italy.—Exploration efforts have been directed offshore in the Adriatic Sea with renewed exploration expected following the 1972 issuance of 21 licenses covering about 1.2 million acres in the Sicilian Channel. A three-well program was planned for drilling beginning during 1972 in water 500 feet deep near the offshore Adriatic Sea boundary with Yugoslavia. At least one company performed seismic surveys in offshore areas of the Tyrrhenian Sea. Most of the country's onshore plans center on natural gas, as crude oil production, all in Sicily, was down to 21,000 barrels per day. The Italian state company, Ente Nazionale Idrocarburi (ENI) continued to work toward strong exploration in foreign regions, especially North Africa and the Middle East.

Jamaica.—The Government reached an agreement in principal with an Italian group in the construction of a new 250,000-barrel-per-day refinery. The plant, like others in the Caribbean area, would serve mainly the United States east coast market.

Japan.—A preliminary agreement was reached between Japan and the Republic of Korea regarding a joint operation in the exploration and development in the offshore Sea of Japan area claimed by both countries. Drilling is expected to commence in the near future.

A strike by Japanese seamen lasted 90 days, the longest in the history of Japan's labor unions. The strike idled 145 tankers totaling 14.5 million deadweight tons and affected the crude oil output of several countries, particularly Abu Dhabi whose principal crude oil exports go to Japan.

With the completion in October of one new refinery and the expansion of nine other plants, Japan's refinery capacity rose by nearly 500,000 barrels per day to a total of 4.7 million barrels per day, the world's third largest after the United States and the U.S.S.R.

The world's largest tanker, the 477,000-deadweight-ton, *Globtik Tokyo* was launched at Hiroshima during October 1972. It is to be completed in early 1973.

Following a favorable report from the Ministry of Health, official permission for petroleum-protein production planning was given. The first two commercial projects will be the 60,000-ton-per-year plant at Gamagori (Shizuoka Prefecture), to be completed in 1974, with provisions for doubling capacity by 1976, and another 60,000-ton-per-year plant at Takasago (Hyogo Prefecture), to be completed in 1973.

Kuwait.—The Government requested the country's major crude oil producing company, Kuwait Oil Co., Ltd. (KOC), owned jointly by British and U.S. firms, to limit oil production to about 2.9 million barrels per day. As the second country, following Libya, to limit production, Kuwait seeks to conserve oil in favor of future higher prices.

Exploration in southwestern Kuwait by KOC resulted in finding a well that tested nearly 2,000 barrels per day. The Spanish company, Hispanica de Petroleos, S. A. (Hispanoil) found oil after drilling two dry wells.

Kuwait Oil Tanker Co., the largest tanker company in the Middle East, purchased two tankers and contracted for a 1973 delivery of a 324,000-deadweight-ton tanker which will bring its total capacity to 1,114,000 deadweight tons.

Libya.—Ente Nacionale Idrocarburi (ENI), the Italian State oil company was finally permitted to export crude from its first Libyan oilfield (Abu Tiffel) after months of negotiations with the Libyan Government. Under the agreement ENI had to forfeit 50% of its ownership of the field to the Government. Reportedly, Libya is to pay ENI for one-half of its cost to find and develop the field. Initial production of 200,000 barrels per day was piped to Zuetina terminal. Production is expected to rise to 300,000 barrels per day.

Less than a week after the agreement with ENI, the Government made a similar demand of Nelson Bunker Hunt's share of the big Sarir field in the Concession 65. In this demand, however, Libya claims half of Hunt's profits from the field, retroactive to December 1971 when the Government seized the half of the field owned by British Petroleum Co., Ltd. (BP).

Malaysia.—Near the end of 1972 the Malaysian Government announced plans to enter production-sharing contracts with oil companies rather than continue the present system of concessions. Present concessions will be respected. Prospects for a substantial oilfield offshore Sabah were encouraging, following the Government announcement that three out of five wells drilled 53 miles northeast of Kota Kinabalu (formerly Jesselton) in the South China Sea have tested at rates of more than 2,000 barrels per day. The concessionaire, an Exxon, Inc., subsidiary, planned to build a fixed drilling platform in the area and rapid development was indicated for Sabah's first oilfield. After 62 years of operation Sarawak Shell Berhad closed its Miri oilfield. It was producing less than 400 barrels per day from 70 of its 624 wells.

Mexico.—Although production increased 4% during 1972, output fell short of sales, which increased 8%. Petróleos Mexicanos (Pemex) had two major discoveries, one offshore and the other onshore, and confirmed the existence of larger quantities of oil than previously estimated in the offshore Arenque field. During the first 8 months of 1972, a total of 278 wells were drilled, of which 165 were productive.

Pemex planned to increase refining capacity by one-third to 930,000 barrels per day in 1976 and to increase pipeline facilities, especially to the interior and from offshore terminal facilities.

Netherlands.—In a third round of exploration license allocations in the Dutch sector of the North Sea, 26 blocks were granted in mid-1972 to 16 companies or groups. Most of the licenses were granted north of the 54th parallel where the new offshore boundary with the West German sector was delineated. All exploration in 1972 resulted in either dry wells or natural gas discoveries. Crude oil output declined 7% to about 30,000 barrels per day.

The country's refining capacity increased a substantial 15% to 1.8 million barrels per day. Plans were to raise this to 2.2 million barrels per day by 1975–76. Included were two of the world's largest refineries, the 540,000-barrel-per-day Pernis plant owned by the Royal Dutch/Shell group of companies and the Rotterdam plant of BP, which will reach 460,000 barrels per day in 1973.

Nigeria.—Major new discoveries announced during the year included the large 18,500-barrel-per-day find 30 miles offshore from Bonny by Occidental Petroleum Corp., in a joint venture with the Nigerian National Oil Corp. The well, which tested 35° API gravity crude from two zones, is the biggest Nigerian discovery. The joint operation of Texaco, Inc., and Chevron Oil Co. made two promising offshore discoveries during the year. The Anyala find 27 miles offshore tested over 5,000 barrels per day from two zones, and the Middleton discovery tested almost 7,000 barrels per day from three zones.

Gulf Oil Corp.'s new Abiteve field, its first onshore field (located 7 miles from the Escravos terminal), came onstream in October and was expected to reach 15,000 barrels per day by yearend.

At yearend total Nigerian production was averaging about 1.9 million barrels per day. The United States and offshore refineries in the Virgin Islands and the Bahamas, were the destination of 27% of Nigeria's crude oil exports. The production growth rate was expected to slow down slightly in 1973 as several small 1970–71 discoveries were expected to come onstream.

Norway.—During the first full year of crude oil production, output averaged about 33,000 barrels per day compared with 5,700 barrels per day in 1971. Production began in June of that year from the offshore Ekofisk field 140 miles west of Stavanger. A giant concrete storage tank (1 million barrels) under construction at Stavanger was scheduled to be moved to the producing area in 1973, and when completed the field should be able to produce 100,000 barrels per day. Phillips Petroleum Co., operator of Ekofisk, concluded an agreement with a U.S. firm for laying a pipeline from Ekofisk field to Teeside on the Yorkshire coast of the United Kingdom at a cost of about $200 million. The contract was subject to final approval by the Storting, Norway's Parliament.

Preliminary estimates place Norway's offshore production potential, based on fields discovered through 1972, at about 1 million barrels per day.

During December 1972 the new Norwegian Government by royal decree stiffened the terms for future offshore exploration agreements by increasing royalties and rentals and by providing for state participation in production without exploration risk.

Oman.—To counter declining production rates, Petroleum Development (Oman), Ltd., launched an exploration program on its onshore agreement area and also placed in operation a water injection program for its Yibal field. The exploration resulted in the discovery of oil in three small structures in the Ghaba area about 60 miles south of the present producing fields.

Peru.—Petróleos del Perú, the state oil company, announced a second discovery in the Amazon basin area of northern Peru. Details of the well were not given, but the first discovery tested 3,000 barrels per day. The location of the new find is remote, and a trans-Andean pipeline will be required to carry the crude to the Pacific coast. However, officials have indicated that a line would be built when reserves are sufficient to sustain a production of 100,000 barrels per day. Earlier, a partnership of two U.S. oil companies discovered oil offshore from Tumbes in the extreme north of Peru. The well yielded a crude having a 39° API gravity from two intervals, one testing more than 1,000 barrels per day.

Philippines.—On September 21, 1972, President Marcos invoked his constitutional powers to assume responsibility for the country's petroleum affairs. This and subsequent legislation made it possible for foreign investors to enter into exploration in the Philippines. The Petroleum Act of 1949 had discouraged foreign investment. As a result of the new legislation, a number of foreign companies responded with proposals following a campaign to encourage exploration by foreign firms. On December 31, 1972, several U.S. petroleum companies and the Philippine Government signed the country's first oil exploration service contract. The area of new interest is off Palawan Island in the Sulu Sea toward Sabah. Exploration on land over many years, carried out by foreign companies in partnership with local interests, has not yielded any commercial oil.

Puerto Rico.—Crown Central Petroleum Corp. announced a project to build a refinery near the port of Guayama which will produce up to 27,000 barrels per day of naphtha and 23,000 barrels per day of fuel oil. It is to be completed in 1975.

Romania.—With production from its older fields on the decline, Romania has entered a stage of diversified research and exploration. Geophysical exploration was being carried out in areas bypassed in the past, secondary recovery methods were being employed in formerly abandoned fields, and the Government has contracted with a U.S. firm to deliver a $3.2 million offshore drilling platform. In addition research was being conducted in the underground combustion of oil shale.

Saudi Arabia.—Saudi Arabia strengthened its position as the world's third largest producer of crude oil. Production rates of about 7 million barrels per day at the close of 1972 suggest that within a few years it may overtake both the U.S.S.R. and the United States. It is expected that production levels will reach 9 million barrels per day by mid-1974.

The expansion program which started in 1971 continued through 1972. Nineteen drilling rigs were in operation at yearend, and despite accelerated production rates, crude oil proved reserves increased by 5 billion barrels, about twice current annual production. Including Saudi Arabia's share of the Kuwait-Saudi Arabia Partitioned Zone, the Government estimated reserves at 157 billion barrels.

Three offshore sea-island tanker loading facilities at Ras Tanura are to be joined by a fourth in early 1973, making the complex the world's largest offshore loading facility. Each of the two berths at the new sea island will have a loading capacity of 280,000 barrels per hour and can handle simultaneously two tankers of from 150,000 to 500,000 deadweight tons. A new loading port is planned for late 1974 which will double the export capacity of the offshore complex to over 10 million barrels per day.

Spain.—The Government approved a variety of offshore and onshore leases during the year, but there was little drilling activity. The several wells drilled were dry.

With surplus refining capacity already available and more anticipated, Spain is in an ideal position to become a major exporter of refined petroleum products. Geographically, the country is located astride major crude oil tanker routes originating in the Mediterranean Sea and the Persian Gulf. Projected refinery surplus is expected to exceed 350,000 barrels per day by 1975.

Syrian Arab Republic.—Immediately following the Iraqi seizure of IPC holdings in Iraq, the Syrian Government nationalized the pipelines that carry crude oil exports from northern Iraq to Mediterranean loading terminals. Exports from Banias, Syria, which fell to a low of 200,000 barrels per day in July, increased rapidly to an average of 744,000 barrels per day in October. At yearend a dispute between Iraq and Syria over transit fees was taking place. Syria was claiming double the fees previously paid by IPC plus a flat annual payment to cover maintenance costs.

Taiwan.—The Government company, Chinese Petroleum Corp. (CPC), continued seismic and gravimetric surveying throughout Taiwan. There were also seismic studies by two companies covering offshore areas. Exploration drilling resulted in one successful oil well, one successful gas well, and four dry wells. Development well drilling resulted in two gas producers and five dry wells.

A U.S. firm concluded a contract with CPC covering the exploration and development of 7 million acres on Taiwan's Continental Shelf in the East China Sea. The triangular area is southwest of, and outside, the area claimed by the Republic of Korea and Japan. It is 110 miles from the Chinese coast, opposite the mouth of the Yangtze River.

Trinidad and Tobago.—Crude oil production continued to decline until August when the offshore Teak (formerly Radix) and Galeota fields came into production. When these two and a third offshore field are brought into full production, it is expected that production will reach 270,000 barrels per day, a national record.

Tunisia.—The two oilfields found in 1971, Sidi el Itayem west of Sfax and the offshore Ashtart field, were put into production at rates of 10,000 and 30,000 barrels per day, respectively. A new field, Sidi Behara with an expected capacity of 12,000 barrels per day, was found 6 miles west of Sidi el Itayem field. The offshore field is being operated from a production platform and a unique mooring buoy which enables tankers to load directly from floating storage tanks. Because of more stringent terms in other North African countries, there has been renewed interest in Tunisian exploration, especially by French and Italian companies. By the end of 1972 much of the onshore area and nearly all of the offshore Continental Shelf was under concession.

Turkey.—Discoveries in 1972 included a field in the Diyarbakir area which was expected to produce 4,000 barrels per day and two others in eastern Turkey which together produced 1,800 barrels per day by yearend. Significantly, two concessions were awarded, one in Western Turkey near Istanbul and the other in the southeast near the Iraqi border. Two U.S. firms announced plans for seismic exploration of nearly 1 million offshore acres in the Marmara Sea from the Bosporus to the Dardanelles. After many years of planning and construction, the Izmir refinery, built with U.S.S.R. assistance, came onstream with a capacity of 66,000 barrels per day.

U.S.S.R.—It was reported at yearend that an agreement in principal was in sight with United States and Japanese interests for the development of some of Siberia's main natural gas resources. The proposed United States-Japanese contribution in development work will count as advance payment for gas shipments to the United States and Japan over 25 years at a combined rate of up to 5 billion cubic feet per day. Involved will be Tyumen and Yakutsk gasfields, and a 1,800-mile, 56-inch pipeline to Murmansk where a liquefaction plant will process Tyumen gas. Yakutsk gas will be shipped via a 2,500-mile, 56-inch pipeline to the Pacific port of Nakhodka. The whole arrangement may involve an expenditure of $50 billion, making it one of the most expensive schemes ever undertaken.

United Arab Emirates.—Production in Abu Dhabi (one of the two emirates having crude production) continued to rise, but because of the Japanese seamen's strike during midyear, the increased rate was lower than those of recent years. An estimated one-third of the production is exported to Japan. Production facilities were being expanded at the onshore fields of Bu Hasa and Asab and the offshore Mubarraz field. With production from the offshore fields of Umm Shaif and Zakum expanded during 1972, it is expected that by 1974–75 total output from Abu Dhabi will reach 2 million barrels daily. A decision on a development scheme for the offshore Bunduq field was pending at yearend.

Negotiations with a West German consortium called Deminex involving the purchase of a share of BP's holdings in Abu Dhabi collapsed. However, at yearend BP was negotiating with a Japanese consortium with other oil interests in Abu Dhabi. In two separate offers, the Government invited bids for offshore exploration areas totaling 6,800 square miles.

Production in Dubai also increased to more than 150,000 barrels per day. Major development was the installation of two large inverted-funnel, bottomless storage tanks to join a similar tank at the offshore Fateh oilfield. Each tank has a 500,000-barrel capacity. A single-buoy mooring capable of handling 300,000-deadweight-ton tankers was also built, making two of that size at Fateh. Dubai production is expected to reach 300,000 barrels per day during 1973.

A promising discovery has been made off the island of Abu Musa in Sharjah waters by Buttes Gas and Oil Co., operator for a group of U.S. companies. The well, in 200 feet of water about 9 miles east of the island, tested 13,955 barrels per day of low-sulfur, 36° API gravity crude oil. Occidental Oil Co., offshore concessionaire for Umm al Quwain, disputes rights in the area and has taken legal action against the group. The dispute stems from action taken by Sharjah in 1970 declaring the width of its territorial waters to be 12 miles instead of 3 miles.

United Kingdom.—Thirty-one exploration wells were drilled in British North Sea waters in 1972, 26 in the northern part and the remainder in the south. In addition 32 development wells were drilled in the British North Sea; all except two were in southern waters. The drilling resulted in several new field finds (Cormorant, Piper, and Beryl), the confirmation of two major fields (Auk and Brent), and the discovery of several natural-gas-condensate fields. Plans are that the large Forties and Auk oilfields will come onstream in 1974 and the Brent field in late 1975.

In March, 246 Fourth Round blocks covering about 23,200 square miles were awarded to 66 companies or combines. During the initial 6 years of these Fourth Round leases, 224 wells are to be drilled west of the Shetland Islands including, for the first time, parts of the Celtic Sea.

Venezuela.—Effective January 1, 1972, tax reference prices were increased an average $0.32 per barrel for crude oil and $0.35 per barrel for refined products. The rising tax-paid cost of Venezuelan crude and declining tanker fees made Middle Eastern crudes more competitive in Venezuela's principal world markets and helped reduce 1972 exports of crude oil. A 9% decline in crude oil production followed. To safeguard its income, the Government applied rules that severely penalize companies for decreasing production below a stipulated amount. In October, the tax reference prices for crude and products applicable to exports in 1973 were officially published effective January 1, 1973. The increases averaged between $0.12 per barrel for crude oil and $0.17 per barrel for refined products. These more recent increases portend future marketing difficulties for Venezuelan petroleum.

Creole Petroleum Corp., a subsidiary of Exxon, Inc., finished a major expansion of its Amuay refinery, raising the capacity to 630,000 barrels per day. Included was an increase from 200,000 to 300,000 barrels per day of desulfurization capacity. Amuay refinery is now the world's largest and represents a total investment of $370 million.

Yugoslavia.—Benicanci, one of the country's most promising fields, came onstream in October 1972. Some 80 wells were drilled in the field through 1972. Production targets are 10,000 barrels per day by the end of 1973. A pipeline was under construction to the Sisak refinery where throughput capacity was increased by 40,000 barrels per day. A second field, Kelebija, which extends across the Hungarian border, began production in early 1972. Stepout wells were drilled at the Velebit oilfield and new gas horizons were discovered at Tilva. In 1975, production from these three and others in the Voivodina is planned at about 20,000 barrels of oil per day and 180 million cubic feet of gas per day.

At yearend, Yugoslavia's lone offshore rig (leased from a French company) was being refitted following the completion of four dry holes off Dugi Otok. Its next assignment will be in the western part of Yugoslavia's Adriatic waters.

Zaire.—In April the Gulf Oil Co. drilled a fourth confirmation well near its 1971 offshore discovery; however, the company was uncertain of the field's promise. Onshore two discoveries were undergoing tests by Gulf to determine if they could be produced commercially. A consortium of foreign oil companies operated by the Belgian firm Petrofina, Inc., found small quantities of oil and gas near the coastal town of Maunda.

Table 2.—Supply, demand, and stocks of all oils in the United States

---

[p] Preliminary.

[1] U.S. Department of the Interior data for crude oil, unfinished oils, and plant condensate; U.S. Department of Commerce data for all other imports.

[2] Represents the difference between supply and indicated demand for crude petroleum.

[3] Minus represents withdrawal from stock, which is added to total disposition; plus represents stocks increase, which is subtracted from total disposition.

[4] U.S. Department of Commerce data.

[5] Liquefied refinery gas.

[6] Liquefied petroleum gas.

[7] Produced at petroleum refineries. Data for LPG for petrochemical feedstocks are included with those for "Liquefied gases."

[8] Includes isopentane.

Table 4.—Estimates of proved crude-oil reserves in the United States on December 31, by State[1]

(Million barrels)

State	1968	1969	1970	1971	1972

Other States [5]	21	19	83	7	7
Total United States	30,707	29,632	39,001	38,063	36,339

[r] Revised.

[1] From reports of Committee of Petroleum Reserves, American Petroleum Institute. Includes crude oil that may be extracted by present methods from fields completely developed or sufficiently explored to permit reasonable accurate calculations. The change in reserves during any year represents total new discoveries, extensions, and revisions, minus production.

[2] Included with "Other States."

[3] Includes offshore reserves.

[4] This number includes the estimate of proved reserves in the Prudhoe Bay Permo-Triassic reservoir, discovered in 1968. This estimate is based on the analysis of extensive engineering and geologic data; however, revisions may be required when actual production performance becomes available.

[5] Includes Arizona, Missouri, Nevada, South Dakota, Tennessee, and Virginia.

Table 5.—Supply and disposition of crude petroleum (including lease condensate) in the United States

(Thousand barrels)

Supply and disposition	1968	1969	1970	1971	1972 [p]
Supply:					
Production	3,329,042	3,371,751	3,517,450	3,453,914	3,455,368
Imports [1]	472,823	514,114	483,293	613,417	811,135
Total new supply	3,801,365	3,885,865	4,000,743	4,067,331	4,266,503
Stock changes:[2]					
Domestic crude	+17,653	−4,668	+10,380	−23,239	−17,064
Foreign crude	+5,570	−2,298	+760	+6,520	+3,811
Unaccounted for [3]	+7,138	−2,561	−7,721	+14,823	+10,201
Disposition by use:					
Runs of domestic crude	3,308,044	3,363,602	3,485,332	3,481,543	3,473,880
Runs of foreign crude	466,316	516,003	482,171	606,266	806,988
Exports [4]	1,802	1,436	4,991	503	187
Transfers:					
Distillate	712	654	743	1,548	944
Residual	4,272	4,334	4,817	4,565	3,322
Losses	4,134	4,241	4,328	4,448	4,641
Total disposition by use	3,785,280	3,890,270	3,981,882	4,098,873	4,289,957

[p] Preliminary except for crude petroleum production.

[1] Bureau of Mines data.

[2] Minus represents withdrawal from stock; plus represents stock increase.

[3] Represents the difference between supply and indicated demand for crude petroleum beginning with 1968.

[4] U.S. Department of Commerce data.

[1] Includes 283,279,000 barrels in Delaware River Valley.

[2] Includes some Athabasca hydrocarbons.

[3] Includes three by trucks.

[4] Alaska, Arizona, Hawaii, Nevada, Oregon and Washington.

[5] Excludes crude oil imported for direct fuel use by pipeline.

p Preliminary. NA Not available.

[1] Includes underground stocks at plants and refineries, in thousands of barrels. At plants: ethane, 1971, 2,431; 1972, 6,143; propane, 1971, 49,721; 1972, 39,340; butane, 1971, 11,178; 1972, 7,917; butane-propane mixture, 1971, 271; 1972, 324; and isobutane, 1971, 8,403; 1972, 7,407. At refineries (includes LRG): propane, 1971, 5,235; 1972, 4,427; butane, 1971, 2,528; 1972, 3,176; butane-propane mixture, 1971, 370; 1972, 260; and isobutane, 1971, 1,218; 1972, 1,236.

[2] Includes No. 4 fuel oil, in thousands of barrels: 1971, 5,160; 1972, 3,723. Data for previous years are not available.

[3] Includes 10,419,000 barrels of foreign crude oil to be burned as fuel. Data for previous years are not available.

[4] Produced at petroleum refineries. Data for LRG petrochemical feedstocks are included with those for "Liquefied gases."

NOTE:—"Stocks at refineries" include stocks at refineries and bulk terminals operated by refining and refined products pipeline companies, including pipeline fill. "Stocks at plants" include stocks at plants and terminals operated by natural gas processing companies and natural gas liquids stocks at terminals of pipeline companies, including pipeline fill.

p Preliminary.

[1] Includes some Athabasca hydrocarbons.

[2] "Other hydrocarbons and hydrogen" is defined as including all hydrogen, process natural gas, tar sand bitumen, gilsonite, shale oil, and other naturally occurring hydrocarbon mixtures consumed as raw materials in the production of finished products.

[3] Production at natural gasoline plants shown as direct transfers and omitted from the input and output at refineries.

[4] Conversion factors: 280 pounds of wax to the barrel; 5.0 barrels of coke to the short ton; 5.5 barrels of asphalt to the short ton.

[p] Preliminary.

[1] Includes some Athabasca hydrocarbons.

[2] Production at gas-processing plants shown as direct transfers and omitted from the input and output at refineries.

[3] Conversion factors: 280 pounds of wax to the barrel; 5.0 barrels of coke to the short ton; 5.5 barrels of asphalt to the short ton.

[p] Preliminary.

[1] Includes some Athabasca hydrocarbons.

[2] Production at gas processing plants shown as direct transfers and omitted from the input and output at refineries.

[3] Conversion factors: 280 pounds of wax to the barrel; 5.0 barrels of coke to the short ton; 5.5 barrels of asphalt to the short ton.

Table 37.—Percentage yields of refined petroleum products from crude oil in the United States[1]

Finished products	1968	1969	1970	1971	1972 p
Gasoline	43.9	44.8	45.3	46.2	46.2
Jet fuel	8.3	8.2	7.5	7.4	7.2
Ethane (including ethylene)	(2)	.2	.2	.2	.2
Liquefied gases	3.1	2.9	3.0	2.9	2.8
Kerosine	2.7	2.6	2.3	2.1	1.8
Distillate fuel oil	22.1	21.7	22.4	22.0	22.2
Residual fuel oil	7.2	6.8	6.4	6.6	6.8
Petrochemical feedstocks	2.5	2.5	2.5	2.7	2.9
Special naphthas	.7	.7	.8	.7	.7
Lubricants	1.7	1.7	1.6	1.6	1.5
Wax	.2	.2	.2	.2	.1
Coke	2.5	2.6	2.7	2.6	2.8
Asphalt	3.6	3.5	3.6	3.8	3.6
Road oil	.1	.2	.3	.2	.2
Still gas	4.0	4.1	4.1	3.8	3.9
Miscellaneous	.4	.4	.3	.4	.4
Shortage	−3.0	−3.1	−3.2	−3.4	−3.3
Total	100.0	100.0	100.0	100.0	100.0

p Preliminary.

[1] Other unfinished oils added to crude in computing yields.

[2] Included with liquefied gases.

[p] Preliminary.

[1] Figures represent crude oil used as fuel on pipelines which is considered part of the demand for distillate.

[2] Includes No. 4 fuel oil in thousands of barrels: PAD district I, 1971, 4,021; 1972, 2,996; PAD district II, 1971, 328; 1972, 336; PAD district III, 1971, 654; 1972, 223; PAD district IV, 1971, 6; 1972, 12; PAD district V, 1971, 151; 1972, 156.

[p] Preliminary.

[1] Represents crude oil used as fuel on leases and for general industrial purposes.

[2] Sulfur content in thousands of barrels: 0%-0.50%—1971, 50,526; 1972, 64,855: 0.51%-1.00%—1971, 57,805; 1972, 70,824. 1.01%-2.00%—1971, 97,824; 1972, 92,652. Over 2.0%—1971, 68,524; 1972, 64,188.

[3] Sulfur content in thousands of barrels: 0%-50%—1971, 109,328; 1972, 203,137. 0.51%-1.00%—1971, 166 606; 1972, 163,764. 1.01%-2.00%—1971, 77,225; 1972, 79,316. Over 2.0%, 1971, 224,541; 1972, 191,184.

[4] Includes 9,989,000 barrels of foreign crude oil to be burned as fuel.

[5] Includes 480,000 barrels of foreign crude oil to be burned as fuel.

[p] Preliminary.

[1] Imports for onshore use of military jet fuel, distillate and residual fuel oils, and receipts from Puerto Rico, the Virgin Islands, and Guam included in these data are based on figures reported to the Department of the Interior. All other import figures are compiled from Department of Commerce data.

---

[p] Preliminary.

[1] Imports of crude and unfinished oils reported to the Bureau of Mines, imports for onshore military jet fuel, distillate and residual fuel oil, and receipts from Puerto Rico, the Virgin Islands, and Guam are based on data reported to the Department of the Interior. All other import figures are compiled from Department of Commerce data.

[2] Includes quantities imported duty-free for supply of vessels and aircraft engaged in foreign trade.

[3] Included in distillate fuel oil.

Phosphate Rock

By W. F. Stowasser [1]

Data for 1972 indicated that demand in the world for phosphate rock exceeded production for the second consecutive year. Estimated world sales in 1972 were 8% higher than sales in 1971. A significant reduction in world stocks reflected efforts to supply the strong demand that developed in 1972

The average unit value of domestic phosphate rock declined from $5.24 in 1971 to $5.09 per ton f.o.b. plant, in 1972. Reasons for the price decline in a period of exceptionally high demand for phosphate rock were not clear. It was speculated that if contracts written in 1970 or the first half of 1971, when prices were depressed, remained in effect through 1972, the increase in domestic and foreign demand would not be reflected by higher prices. The effect of Phase II price controls during 1972 restrained domestic prices and was in part responsible for shifting sales of phosphate rock into the more profitable export market. However, increased competition from North African phosphate rock producers limited phosphate rock price increases in world markets.

Although the demand for phosphatic fertilizers was strong, the demand for elemental phosphorus for industrial purposes was depressed because of restrictions on permissible levels of sodium tripolyphosphate in detergents.

Legislation and Government Programs.—The emphasis of legislative and Government actions was directed toward environmental problems. The Federal Bureau of Mines met with the Board of Directors of the Florida Phosphate Council in response to the phosphate industry's request for Federal aid to find a solution to the phosphate slime dewatering problem. The Bureau of Mines proposed research programs supported by a cost-sharing agreement. The proposal was accepted. The program is described in the technology section of this chapter.

The Governor of Florida signed into law, bills providing for coordinated management of Florida's water resources, purchase of environmentally endangered forests, and State control of land use development. The "Florida Environmental Land and Water Management Act of 1972" will have an effect on the phosphate mining industry. The section on water management gives the Department of Natural Resources the power to conserve, protect, and manage all the waters of the State. The Department of Natural Resources will establish a State-wide water use plan that will impose regulations on well drilling and all consumptive uses of water. The land use section allows the State to purchase or rigidly control development of about 5% of the State's land area. These lands will be designated to be of critical concern to the State and be protected.

The Florida Pollution Control Board adopted safety regulations designed to prevent damaging slime spills from holding ponds associated with phosphate rock processing operations. The Board tightened requirements for construction, operation, and maintenance of dams designed to retain the slimes from the phosphate ore washing plants. The new rules set minimum standards on the dams and emphasized intensive surveillance by State inspectors.

In the suit filed by the Florida Department of Pollution in Polk County Circuit Court, after a slime pond dam broke on December 3, 1971, $10 million in compensation damages and $10 million in punitive damages were sought from Cities Service Co. The punitive damage part of the suit was removed by the Circuit Court and the compensatory damage permitted to stand.

The Attorney General of the State of Florida has renewed his request for a hearing on his motion for a preliminary injunction against the issuance of phosphate mining leases in the Osceola National Forest. The State filed suit in 1971 against the Secretaries of the U.S. Department of the Interior and the U.S. Department of Agriculture after it was disclosed that preferential rights leases had been applied for by several companies in the Osceola National Forest. A moratorium was placed on the issuance of leases by the Secretary of the Interior to permit completion of environmental impact statements. The Attorney General contended that the Environmental Protection Act and other statutes superseded the mining laws that direct the Federal Government to issue mining permits if conditions specified are met.

---

[1] Physical scientist, Division of Nonmetallic Minerals.

The Governor of Tennessee signed into law House Bill 1519, which became effective on March 23, 1972. This bill repeals the old strip mine law and gives the State of Tennessee one of the strongest surface mining statutes in the Nation. The phosphate industry may be prohibited from strip mining in areas if this activity will cause severe environmental damage or in areas where the disturbed land cannot be reclaimed. Strict regulations are specified for mining methods, reclamation plans, disposal of overburden, regrading, and revegetation procedures.

A 5% corporate profit tax was enacted by a special session of the Florida State legislature in December 1971, and will affect the phosphate industry in Florida in 1972. The corporate profit tax was predicted to generate approximately $150 million per year.

On April 1, 1972, the State of Florida received its initial payment under the severance tax law enacted in 1971. A total severance tax of $1,221,659 was due for phosphate rock mined from July 1 through December 31, 1971. This initial 6-month payment was based on a 3% assessment rate. This rate will increase to 4% on July 1, 1973, and 5% July 1, 1975. The value per ton of phosphate rock assigned by the Department of Revenue for tax purposes was $3.11. Of the $1,221,659 total, $258,718 was deductable as ad valorem tax credits paid to counties in which the companies operated, one-half of the remainder, $481,470 was returned to the industry for land reclamation, and the remaining $481,470 was deductable from Federal taxable income. The latter resulted in a Federal tax credit of $231,105. These deductions and tax credits reduced actual payments to the State by industry to $250,354 for the 6-month period.

A new State-wide ban on high-phosphate detergents was announced by the Florida Pollution Control Board. Effective the first of 1973, the rule limits the phosphorus content of soaps and detergents to 8.7%. This is the same ceiling imposed by the States of Connecticut, Indiana, Maine, Michigan, and New York. Dade County, Fla., has banned the sale of detergents containing any phosphorus. Some cities, including Chicago, Ill., and Buffalo, N.Y., have total bans on phosphate detergents. The Florida ceiling of 8.7% phosphorus content in detergents applies only to laundry products, not to automatic dishwashing detergents or personal hygiene products such as shampoo or toothpaste. Detergents sold for industrial or institutional use were also exempted from the phosphorus limitation.

DOMESTIC PRODUCTION

Domestic production of marketable phosphate rock was 40,831,000 tons, a 5% increase over that of 1971. The value of the marketable rock was $207,910,000, a 2% increase over that of 1971. The average grade of phosphate ore mined in the United States was 14.7% P_2O_5, and the average grade of marketable rock was 31.4% P_2O_5. The average weight recovery of concentrate and marketable rock as mined was 32.2%, and the P_2O_5 recovery averaged 69.2%. Of the total production in the United States, Florida and North Carolina produced 34,121,000 tons (83.5%), the Western States produced 4,555,000 tons (11.2%), and Tennessee produced 2,154,000 tons (5.3%).

Florida and North Carolina.—Production of marketable phosphate rock was 34,121,000 tons, an increase over that of 1971 of 1,970,000 tons, or 6.1%. The value of marketable rock increased to $173,910,000, an increase over that of 1971 of $6,157,000, or 3.7%.

The average grade of phosphate ore mined was 13.9% P_2O_5, and the average grade of marketable rock was 32.2% P_2O_5. The average weight recovery of concentrate and marketable rock as mined was 29.1%, and the average P_2O_5 recovery was 67.4%.

Companies operating in the Florida land-pebble phosphate fields were Agrico Chemical Co., Borden Chemical Co., Brewster Phosphates, Cities Service Co., W. R. Grace & Co., International Minerals and Chemical Corp. (IMC), Mobil Chemical Co., Poseidon Mines, Inc., P.S.A. Enterprises, Occidental Chemical Co., Swift Agricultural Chemical Corp., and U.S.S. Agri-Chemicals, Inc. Soft rock operators were Howard Phosphate Co., Kellogg Co., Loncala Phosphate Co., Manko Co., Inc., and Sun Phosphate Co.

Texas Gulf, Inc., Lee Creek, N.C., announced that they would increase phosphoric acid capacity by 525 tons per day of P_2O_5.[2] The expansion is scheduled to be completed in 1974.

The Agrico Chemical Division of Continental Oil Co. (Agrico) was sold to the Williams Cos., Tulsa, Okla., Agrico will become a part of Willchemco, Inc., a division of Williams.[3] Agrico announced a $50 million expansion at its Donaldsonville, La., plant to increase the phosphoric acid capacity by 400,000 tons per year of P_2O_5.[4]

IMC and Fertilizantes Fosfatados Mexicanos, S.A. plan to construct a fertilizer complex in central Florida. The $80 million plant will be operated by IMC to produce diammonium phosphate and triple superphosphate. Production of 600,000 tons per year is scheduled for 1974.[5]

CF Industries, Inc., plans to double the size of its Plant City, Fla., fertilizer manufacturing complex.[6] The expansion will increase finished product capacity to 650,000 tons per year of fertilizer. The expansion at Plant City will include a 250,000-ton-per-year phosphoric acid train, two 1,000-ton-per-day sulfuric acid plants, and two granulation units. Scheduled production in 1972 was 4.9 million tons, 5.2 million is planned for 1973, and higher production is anticipated by 1976. Phosphate rock will be purchased from Florida suppliers.

Conserv Chemicals, a division of Conserv, Inc., Lakeland, Fla., plans to reopen the plant purchased from Mobil Oil Corp. in 1971.[7] After modernization and renovation at a cost of several million dollars, the plant is scheduled to start up in 1973 to produce phosphoric acid and fertilizers.

The Phosphate Rock Export Association (Phosrock) that was formed in 1971, established headquarters in Tampa, Fla., in 1972 and after July 1, 1972, handled the sales, supply, and distribution of phosphate rock in the export market of its five member companies. They are Agrico Chemical Co., American Cyanamid Co., W. R. Grace & Co., International Minerals and Chemical Corp., and Occidental Chemical Co.

Western States.—Production of marketable phosphate was 4,555,000 tons, a 9.4% increase over that of 1971. The value of the marketable rock decreased to $23,268,000 or 2.7% below that of 1971. The average grade of mined phosphate ore was 26% P_2O_5, and the average grade of marketable rock was 28.4% P_2O_5. The weight recovery of concentrate and marketable rock as mined averaged 81.9%, and the average P_2O_5 recovery was 89.1%.

[7] Tampa Tribune. New Phosphate Firm To Begin Fertilizer Production in 1973. Dec. 21, 1972, p. 13.

In Idaho, Agricultural Products Corp., Monsanto Co., J. R. Simplot Co., and Stauffer Chemical Co. mined and processed phosphate rock. Cominco American, Inc., mined phosphate rock in Montana. This was the only active underground phosphate mine in the United States. Stauffer Chemical Co. mined phosphate rock in two areas of Utah and also mined phosphate rock in Wyoming.

The Meramec Mining Co., Sullivan, Mo., produced an apatite concentrate from the tailings from the Pea Ridge iron ore mine during the period from 1964 through 1967. This material was marketed in 1972 for phosphoric acid production and will continue to be marketed in the future for this purpose.

Beker Industries, Greenwich, Conn., acquired the superphosphoric acid and diammonium phosphate plant at Conda, Idaho, from El Paso Natural Gas Co. This plant plus the assets of the Mountain Fuel Supply Co., which includes the mine and benefication plant, were the components that formed the Agricultural Products Corp. The first year of production for this company was 1972.

Tennessee.—Production of marketable phosphate rock was 2,154,000 tons, a decline of 417,000 tons or 16.2% from that of 1971. The value of the marketable rock declined 11.7% below that of 1971.

The average grade of phosphate ore mined was 21.4% P_2O_5, and the average grade of the beneficiated rock was 26.1% P_2O_5. The average weight recovery of concentrates was 56.3%, and the P_2O_5 recovery averaged 68.9%.

Hooker Chemical Co., Monsanto Co., Stauffer Chemical Co., and the Tennessee Valley Authority (TVA) mined phosphate rock in Tennessee for production of elemental phosphorus from electric furnaces. Restrictions on the quantity of sodium tripolyphosphate in detergents has reduced the demand for elemental phosphorus from the Tennessee furnaces.

CONSUMPTION AND USES

Apparent consumption of marketable phosphate rock increased 6.3% above that reported in 1971.

According to producers' reports, the quantity of marketable rock sold or used was 43,755,000 tons. This was an increase of 8.6% compared with the quantity sold or used in 1971. The domestic market consumed 67% of this total and 33% was exported.

The consumption pattern in the United States was 24,019,000 tons (81.5%) for fertilizer, 5,173,000 tons (17.5%) for elemental phosphorus production, and 289,000 tons (1.0%) for defluorinated rock and other purposes.

The percent distribution by grade of marketable rock in the United States was as follows:

Grade, percent BPL [1]	Distribution (%)
less than 60	9.5
60–66	6.3
66–70	40.5
70–72	10.3
72–74	22.1
Over 74	11.3

[1] 1.0% BPL (bone phosphate of lime or tricalcium phosphate) = 0.458% P_2O_5.

Florida and North Carolina.—The quantity sold or used increased 11.3% compared with the quantity reported in 1971. The quantity sold or used in the domestic agricultural market was 63% of the total sold or used. The balance, 37%, included exports and a minor quantity for industrial applications.

The consumption pattern of the domestic fraction was 22,889,000 tons (98.0%) for fertilizer, 177,000 tons (0.8%) for elemental phosphorus, 289,000 tons (1.2%) for defluorinated rock, and other purposes.

The percent distribution by grade of marketable rock sold or used from Florida and North Carolina was as follows:

Grade, percent BPL	Distribution (%)
Less than 60	0.1
60–66	5.1
66–70	44.8
70–72	11.2
Over 72	38.8

Western States.—The quantity of marketable rock sold or used increased 1.8% compared with 1971 reported sold or used. Of the total sold or used in the domestic and export markets, 25% was used for agricultural purposes. The pattern of the domestic market was approximately 70% consumed in electric furnaces and 30% used to produce fertilizer. Fifty percent of the marketable rock was less than 60 BPL and the balance distributed in higher grades.

Tennessee.—The quantity of marketable rock sold or used declined 13.7% from that of 1971. All of the marketable rock was consumed domestically and was charged to electric furnaces to produce elemental phosphorus. Curtailment of sodium tripolyphosphates in detergents was responsible for the decline in consumption of phosphate rock in Tennessee.

STOCKS

The operating practices of phosphate mining companies in the Western States, Tennessee, and Florida and North Carolina differ with respect to creating stocks of marketable rock. In the Western States, sufficient ore is mined during the mild months of the year to sustain the plants over the winter months. The stocks are depleted when mining is resumed and stocks are not carried over into the next year. Stocks are not maintained in Tennessee.

Stocks are maintained in Florida and North Carolina. Yearend stock of marketable phosphate rock declined from 11,951,000 to 10,513,000 tons, a decrease of 12%. This reflected the heavy demand from both domestic and export markets in 1972.

PRICES

Prices quoted by the Chemical Marketing Reporter for various grades of Florida land-pebble phosphate rock are shown in table 8. These prices are unchanged from 1971 and only reflect a basis for price negotiation between buyer and seller. Tennessee and Western States phosphate rock prices are not published because most of the rock is consumed by the mining companies to produce elemental phosphorus or fertilizer intermediates or end products. The actual prices of Florida and North Carolina phosphate rock sold to either domestic or export markets are not published.

The average 1972 unit value of marketable phosphate rock reported by producers was $5.09 per short ton f.o.b. plant. This was a decrease from $5.24 per ton in 1971.

The average unit value of marketable rock sold or used in the domestic market from Florida and North Carolina declined from $5.24 per ton in 1971 to $5.10 per ton in 1972. In the Western States, the unit value of marketable rock sold or used declined from $5.69 per ton in 1971 to $5.13 per ton. The unit value of marketable rock sold or used in Tennessee increased from $4.73 per ton in 1971 to $4.99 per ton in 1972.

The average unit value of marketable phosphate rock exported increased from $5.15 per ton f.o.b. plant, in 1971 to $5.28 per ton in 1972, or 2.5%. The unit value of marketable rock exported from Florida and North Carolina increased 2.8% from 1971 to 1972. The unit values increased from $4.96 to $5.10 per ton f.o.b. plant. The unit value of marketable rock exported from the Western States was $8.68 and $8.76 per ton f.o.b. plant, for 1971 and 1972 respectively. This represented an increase in unit value of 1.0%. Tennessee rock was not exported.

Phosrock, Tampa, Fla., increased prices by $1 per ton on all grades of Florida phosphate rock supplied to export markets. Effective July 1, 1972, f.o.b. Tampa or Jacksonville, the following prices were published for new and renewed contracts.

Grade, % BPL	Price per long ton
66–68	$8.70
70–72	10.02
72–73	10.30
74–75	11.18
76–77	12.28

The Office Cherifien des Phosphates raised the listed prices of all grades of Moroccan phosphate rock $1 per ton effective January 1, 1973, assuring price increases of this order to the West European market.[8] Other major suppliers to the West European market are expected to adjust their prices upward and in line with this general trend.

Table 8.—Prices of Florida land-pebble, unground, washed and dried phosphate rock, in bulk, carlots, at mine, in 1972

(Per short ton)

Grade, % BPL	Price
66–68	$6.50
68–70	7.50
70–72	8.15
74–75	9.20
76–77	10.20

Source: Chemical Marketing Reporter.

FOREIGN TRADE

Industry reported that 14,275,000 tons of marketable phosphate rock was exported in 1972. This was an increase of 13.4% over 1971 exports. Most of the phosphate rock was exported from Florida. Exports from Florida increased significantly over those in 1971.

Exports of phosphate rock from the Western States to Canada increased somewhat over those in 1971. The average unit value per ton as calculated from producers' reports was slightly higher than the unit value calculated for 1971.

Analysis of import data showed that 54,738 tons of phosphate rock was imported. This was 35% less than that reported in 1971. The reports show imports of low-fluorine rock, 40,115 tons from the Netherlands Antilles and 9,111 tons from Mexico, and a shipment of 5,512 tons from Spanish Sahara. The total value of these imports was $1,416,000. The average unit value was $25.75 per ton. Imports are expected to continue to decline.

WORLD REVIEW

The production of phosphate rock from over 30 countries is summarized in table 15. With the exception of the operations in the United States, the majority of phosphate rock production in the rest of the world is from Government-owned operations. They are important to their respective countries to the degree that the industry creates employment and, in several instances, is the principle source of foreign exchange.

Algeria.—The State-owned company, Sonatrach, is planning a significant increase in production of phosphate rock from the Djebel Onk mine for the fertilizer complex at Annaba.[9] The current production of 600,000 tons per year of high-grade material will be increased by an additional 600,000 tons per year of low-grade material that will be used in the expanded fertilizer complex at Annaba. This level of production is expected to be obtained in 1975.

---

[9] European Council News. V. 22, No. 540, July 7, 1972, p. 14.

The second stage of the planned expansion is now being studied and, if approved, an additional 600,000 tons of ore will be required by the Annaba complex in 1977. Long-range plans anticipate that by 1980 a total of 2.4 million tons per year of phosphate rock will be processed by the Annaba fertilizer complex.

Angola.—The Government has funded the construction of an artificial island, at a 60 foot water depth, connected to the mainland by a 1 mile pier to permit loading deep draft bulk cargo vessels. Clark Canadian Exploration Co. has acquired a 35% interest in Cia. dos Fosfatos de Angola SARL from the Rockefeller family. Remaining shares are owned by private interests in the United Kingdom and Portugal. A schedule to mine and export the phosphate deposits in the Cabinda exclave has not been announced.

Australia.—Broken Hill South, Ltd., is continuing beneficiation and transportation studies of phosphate rock in northwest Queensland. If the project proceeds on schedule, the earliest that concentrates will be available is the late 1970's. The feasibility of a 150-mile pipeline from the deposits to the Gulf of Carpentaria to transport the concentrates as a slurry is being studied.[10]

Brazil.—Serrana S.A. de Mineração at its Jacupiranga mine in the State of São Paulo, mines and beneficiates phosphate bearing igneous rock.[11] In the new beneficiation plant, apatite is floated from the calcite and magnetite to upgrade the concentrate to 36%–38% P_2O_5. From 1.4 million tons per year of ore, 157,000 tons per year of apatite concentrates are produced. A cement plant was scheduled to start production in 1972 and will use the flotation tailings from the phosphate beneficiation plant.

Israel.—Phosphoric acid production declined because of technical difficulties with the Arad Chemical Industry phosphoric acid plant.[12] Although the plant was shut down in early 1972, it was scheduled to be back on stream before the year was out. Domestic rock is acidulated with hydrochloric acid produced from Dead Sea magnesium chloride. The phosphoric acid plant is rated at 166,000 tons per year of P_2O_5. The acid will be marketed in Europe.

Mexico.—Fertilizantes Fosfatados Mexicanos, S.A., announced plans to build a new plant at Coatzacoalcos, Veracruz, to produce liquid fertilizer grade phosphoric acid.[13] Most of this production is destined for export. The new plant will have an initial capacity of 100,000 tons of P_2O_5 per year.

Morocco.—Production of phosphate rock for the year was 16,503,000 tons, an increase of about 25% over the comparable period in 1971.[14] A goal of 16.5 million tons has been established for 1973, and the Office Cherifien des Phosphates has planned new investments to assure production increases during the 1973–78 period. Incremental expansions of mining, beneficiation, and calcining plants are planned. Increased production of from 1 to 2 million additional tons each year is probable if these plans materialize.

Peru.—The Peruvian Government published a resolution in January 1972 that specified that all mining concessions belonging to Ciá. Minera Bayovar, S.A. would revert to the state.[15] The company had not complied with the General Mining Law requiring submission of development plans. The Sechura Desert phosphate rock deposits were most recently held by the Canadian company Minerales Industriales del Peru S.A.

Senegal.—Sales by the Compagnie Senégalaise des Phosphates Taiba were in excess of 1.5 million tons in 1972.[16] Stocks were reduced to meet this demand. Production capacity will be increased from the present level of 1.4 million to about 1.7 million tons per year.

Spanish Sahara.—Test shipments of phosphate rock from Fosfatos du Bu-Craa S.A. were made to several countries in 1971.[17] Completion of production and shipping facilities appears certain to be completed in 1972 to permit full-scale production of 3 million tons of phosphate rock in 1973. Zen-Noh, the Japanese National Federation of the Agriculture Cooperative Association, and Mitsubishi confirmed that they would receive shipments of Spanish Sahara phosphate rock in 1973.

[17] Fertilizer International. Zen-Noh Sounds Fosbucraa's Capabilities. No. 38, October 1972, p. 2.

Togo.—The Compagnie Togolaise des Mines du Bénin operated at its designed capacity of 2 million tons per year of phosphate rock. An additional investment of approximately $16 million in new mine and plant will be made to increase production to 2.6 million tons per year.[18]

Tunisia.—A new phosphoric acid plant in Gabes started production in February of 1972.[19] The plant is owned by Industries Chimiques Maghrébines, a Government-owned company in which French and Italian organizations have participating interests. The capacity is 120,000 tons of phosphoric acid (P_2O_5) per year. The plant utilizes Tunisian phosphate rock. The concept of building phosphoric plants at locations where raw materials are relatively cheap and shipping the acid to markets may be a trend that will show increasing acceptance in the future.

U.S.S.R.—The U.S.S.R. announced plans to increase production from the Kola apatite combine to 15.3 million tons per year of apatite concentrate by 1975.[20] Current total U.S.S.R. production is estimated to be about 25 million tons per year. In the past, the U.S.S.R. marketed large quantities of apatite in western and eastern European countries. It appears that exports have been restricted and the U.S.S.R. will consume most of its own production. With this development, Florida phosphate rock was imported into eastern Europe for the first time. Although it was assumed that the U.S.S.R. had very large reserves of economically recoverable phosphate rock, there are indications that the reserves are less than were estimated.

TECHNOLOGY

A research program to attempt to solve the problem of disposing of waste phosphate slimes produced from beneficiating Florida and similar type phosphate rock was started.[21] The Florida Phosphate Council, representing 10 operating Florida companies, and the Federal Bureau of Mines are sponsoring the work with the cost of the program equally shared. The purpose of the program will be to develop an economically acceptable procedure to dewater slimes. If this can be accomplished, construction of earth dams to impound the slimes will not be necessary, and the slimes as well as the sand tailings can be used to reclaim mined land. The technology could be advantageously applied to North Carolina, Tennessee, and possibly Western State phosphate tailings.

Experimental studies by the Bureau of Mines to recover phosphates and metals from phosphate sludge generated from phosphate coating processes indicate that the process is technically feasible and economically attractive. Trisodium phosphate, zinc, and iron are recovered. After the sludge is dissolved in hydrochloric acid, the iron as ferric chloride is concentrated in isopropyl ether, zinc is extracted by 2-diethylhexyl phosphoric acid in kerosine, and phosphate is recovered by crystallization from the raffinate.

Additional details have been released about the Kellogg-Lopker phosphoric acid process after 4 years of continuously operating a 240-ton-per-day unit at Whitehaven, England.[22] The main points of interest about this process are that the feed phosphate rock does not have to be finely ground to assure unreacted P_2O_5 from passing through the process, and that the conditions in the reaction system can be controlled to the degree that optimum crystallization of gypsum can be quickly attained and maintained. The increased process flexibility with higher P_2O_5 throughput for equivalent equipment size has not been attained before according to the developers.

The Tennessee Valley Authority demonstrated several new fertilizer production procedures.[23] Some of these will reduce costs as well as permit their adoption by small operators. Briefly, they are a pipe reactor method of producing polyphosphate-enriched solutions; a method of coating urea with sulfur; and a two-stage ammoniating procedure to produce better ortho suspensions.

Nearly all phosphate rock contains fluorine, which is liberated as hydrogen fluoride during wet process phosphoric acid manufacture.[24] If hydrogen fluoride is permitted to escape into the atmosphere, it will create a health hazard. Several processes have been developed to purify fluosilicic acid after it is formed from hydrogen fluoride reacting with silica. APV-Mitchell, Ltd., developed technology for purifying fluosilicic acid and constructed a plant for Tohoku Hiryo KK at Akita, Japan, to produce 18% fluosilicic acid containing only 40–50 ppm P_2O_5. A new process has been developed in Romania to manufacture cryolite from fluorine liberated from phosphate rock during fertilizer manufacture. Fluosilicic acid is treated with sodium chloride to form sodium silicofluoride, reacted with sodium carbonate to produce a sodium fluoride solution, and reacted with sodium aluminate to form cryolite.

[24] The British Sulphur Corp., Ltd. Fluorine. No. 57, January–February 1972, p. 60.

Lancy Laboratories of Zelienople, Pa., has devised a simple method of recovering phosphoric acid from waste aluminum plating solutions. A 28-foot-high column filled with Rohm & Haas ion exchange resin 410 can process up to 70 gallons of waste per day. Food-grade phosphoric acid is eluted from the column periodically with water. The system is expected to find broad application in the automobile and electronic industries.

The M. W. Kellogg Co. is making an engineering feasibility study for Multi Minerals, Ltd., of Canada, of a process that will produce phosphoric acid from monocalcium phosphate.[25] The Multi Minerals' process uses a regenerable ion-exchange resin to convert monocalcium phosphate into phosphoric acid.

Heurtey S.A. has announced a new wet process for the manufacture of phosphoric acid.[26] The process is of the hemihydrate/dihydrate type with the product acid taken at high concentration from the hemihydrate filtration stage. The process is an extension of the Singmaster and Breyer process and has been tested in a 1.5-ton-per-day pilot plant of Compagnie Française de l'Agote at Bassens.

A dry separator developed by the National Research Development Corp. and manufactured by Dryflo Separators, Ltd., of England, has shown it is capable of concentrating a number of minerals including phosphate rock by an entirely dry technique. The ore is fluidized above a porous deck, and as it is moved down a restricted trough, it is stratified according to its density or particle size. A movable splitter separates the fractions of different densities.

A number of research projects were underway at the Bureau of Mines Albany Metallurgy Research Center. These were (1) the recovery of fluorides from phosphate rock, (2) direct acidulation of phosphate ore with sulfuric acid, specifically, land-pebble phosphate ore from Florida to minimize slime formation, and (3) a study of processes to separate phosphate minerals from carbonates in western phosphate ores.

Platinum-Group Metals

By J. M. West [1]

On the strength of a sharp upturn in consumption and growing anticipation that relatively large quantities of platinum-group metals might be needed within a few years for automotive exhaust control, platinum prices and world production posted significant increases in 1972. By the second quarter, U.S. dealers' prices for platinum and palladium had exceeded producers' prices. By early May, the dealers' price for iridium had rocketed from $145–$148 to $525 per ounce, settling back thereafter.

During the year, U.S. mine and secondary production declined 5% and 8%, respectively. However, refinery output of new metal, mainly from imported concentrates and matte, nearly doubled. The volume of metal refined on toll declined, mainly because of a drop in palladium recycling. Imports rose about 534,000 ounces; exports rose 134,000 ounces; stocks, including those on the Mercantile Exchange, rose 69,800 ounces; and sales rose 294,100 ounces. Overall sales were up 23% over those in 1971, with gains in sales of each platinum-group metal. The most significant increase was in sales of platinum, which rose 26%; iridium and ruthenium sales expanded greatly as a result of new chemical and petroleum uses.

World production of platinum metals rose 13% in 1972, owing to mine and refinery expansions in the Republic of South Africa and the U.S.S.R. Canadian production declined because of production cutbacks in the nickel industry, thereby limiting byproduct platinum output. The bulk of the South African production continued to be platinum, while the bulk of the U.S.S.R. production was palladium.

Concerns mounted in 1972 over whether established sources of new platinum could supply all the requirements for emission control devices that would be forthcoming with enforcement of new U.S. air quality standards. Producers and processors were active in reassuring potential consumers and Government agencies involved that adequate supplies could be made available if given adequate lead time to expand facilities. A number of provisional supply/purchase contracts were signed during the year by automakers. Major expansions were underway at yearend.

[2] Includes 2,204 troy ounces nonstockpile grade material.
[3] Includes 2,566 troy ounces nonstockpile grade material.

DOMESTIC PRODUCTION

Domestic mine production of platinum-group metals declined 5% in quantity and 7% in value in 1972. Production from a platinum dredging operation at Goodnews Bay, in Southwestern Alaska, remained virtually unchanged. small amounts of placer gold were also recovered from this venture. The bulk of the platinum-group metals produced—chiefly palladium but with a significant amount of platinum—was recovered from copper refining, the platinum group-metals accompanying gold and other precious metals in the final stages of electrolytic treatment.

Refinery production of new platinum-group metals dropped 27%, with decreased outputs of every metal except iridium and osmium. Also secondary production declined 8% overall, mainly as a result of a sharp drop in secondary platinum refining. Ruthenium and osmium refining were also down.

Toll refining declined 6% in 1972 to a total of 1,361,623 troy ounces. Used material accounted for 94% of the total toll refined; the balance was virgin material, mostly from overseas sources. The United States continued to refine on toll a substantial amount of crude platinum or matte from Colombia, and some from Canada and the Republic of South Africa, although the total crude treated, 84,219 ounces, was down 64% from the 1971 amount. The total quantities treated on toll in 1972 and

CONSUMPTION AND USES

Platinum-group metal sales to consuming industries rose 23% in 1972 to 1.56 million ounces. Increases were recorded for every metal as follows, in percent: Platinum, 26; palladium, 15; iridium, 143; osmium, 13; rhodium, 34; and ruthenium, 143. Most categories of consumption were higher, with uses in the chemical industry showing the most significant advance.

Sales of platinum rose to nearly 543,000 ounces, 42% of which went to the chemical industry. The chemical sales were 67% higher than in 1971. Platinum sales for petroleum refining dropped 32%, on the other hand, apparently because of a slowdown in new refinery construction. Sales to glass manufacturers declined, but manufacturers of electrical equipment used nearly 78% more platinum in 1972. Other uses also rose, including miscellaneous, which more than doubled.

Palladium sales rose 15%, with increases in nearly every category with the exception of electrical, which declined slightly. Dental and medical sales of palladium rose 53%. Electrical and chemical sales comprised 49% and 33%, respectively, of all palladium sales in 1972.

Iridium sales rose 143%, largely as a result of a sharp rise in sales to the petroleum industry for catalytic use. Petroleum accounted for only 3% of all iridium sales in 1971 but rose to 44% of sales in 1972. Sales for glassmaking were down sharply, apparently because of substitution by rhodium. Sales of osmium were 83% to the chemical industry, up from 70% in 1971. The pattern of rhodium sales was not much different than in 1971, except for the jump in sales for glass manufacture to 30% of total rhodium sales. Ruthenium sales boomed in chemical uses, rising nearly 300% in that category. Sales in 1972 were principally for chemical (75%) and electrical (12%) products.

Uses of platinum-group metals remained largely related to their unique catalytic properties, corrosion resistance, high electrical conductivity, reflectance, and physical strength under adverse conditions. One of the major uses was in the chemical industry for nitric acid production through the oxidation of ammonia employing a platinum-rhodium gauze. An estimate of the annual replacement costs—$9.7 million—for this market was published.[2] The petroleum refining industry was reported to be changing from use of monometallic platinum catalysts for reforming to a variety of new bimetallic catalysts. including platinum-rhenium, platinum-iridium, and possibly also platinum-germanium and platinum-indium.[3] The iridium catalyst development sparked an intensive search during the year for new sources of supply. Bimetallics were said to permit reforming at lower pressures and, as a result, gave longer catalyst life and greater octane yield. It was reported that bimetallics, while accounting for 30% of installed reforming capacity, were taking 75 to 80% of the replacement market in 1972.

Development of platinum-based automotive exhaust emission control catalysts continued during the year spurred by requirements of the Clean Air Act of 1970 and subsequent rulings under the Environmental Protection Agency's proposed standards. In pursuing efforts to meet the 1975 requirements, a variety of combinations of platinum and other potential conversion compounds in or on various supporting media were under test. Generally, a combination of platinum and palladium in a 5:2 ratio was found acceptable, with possibly a small addition of ruthenium or other platinum-group metal.[4] Estimates for the precious metal values involved in each unit ranged, generally, from $5 to $15. Overall cost per converter unit, containing coated ceramic pebbles or a ceramic honeycomb structure, was substantially higher owing to fabrication expense. Problems of use and maintenance of emission controls were outlined.[5] Most car manufacturers had made some commitment by yearend to purchase or manufacture platinum-based catalytic devices for their automobiles. Meanwhile, industry efforts were directed toward development of new types of engines or other means of propulsion that would be efficient but non-polluting.

Availability of a special palladium catalyst on a ceramic support was announced for use in controlling nitric acid pollution, especially from nitric acid plants but also from incinerators, etc., that may require controls when new standards are passed.[6] A platinum metals catalyst of undisclosed composition found use in small quantities for safety purposes in nuclear reactors by preventing hydrogen from reaching explosive concentrations.[7] A new rhodium plating process was announced for producing a highly reflective decorative finish,[8] and favorable electroplating properties of rhodium were described.[9] Alloy Metals, Inc., introduced a group of new silver-palladium-aluminum alloys for brazing titanium, beryllium, zirconium, and dissimilar metal assemblies.[10]

[r] Revised.

STOCKS

Stocks of platinum-group metals held by refiners, importers, and dealers increased 5% during the year, to 896,677 ounces. Increases in stocks of individual metals were as follows: Palladium, 28%; rhodium, 11%; and ruthenium, 1%. Platinum, iridium, and osmium stocks fell 12%, 9% and 86%, respectively. In addition, there were Government stocks of platinum, palladium, and iridium, as detailed earlier. (See p. 2.)

Table 6.—Refiner, importer, and dealer stocks of platinum-group metals in the United States, December 31

(Troy ounces)

Year	Platinum	Palladium	Iridium	Osmium	Rhodium	Ruthenium	Total

1972 [1]	392,435	405,793	14,987	82	56,967	26,413	896,677

[1] Stocks in the Mercantile Exchange depositories as of Dec. 29, 1972, were platinum, 49,900 troy ounces, and palladium, 20,400 troy ounces.

PRICES

The producers' price for platinum rose from $120–$125 to $130–$135 per ounce in July and remained at that level to the yearend. The palladium producers' price began the year at $36–$38 per ounce, rose several times reaching $60–$61 in November, and rose again in December to $68–$70 per ounce. Iridium rose about midyear from $150–$155 to $150–$195 per ounce. The producers' prices for the other platinum metals remained unchanged during the year, as follows: Osmium, $200–$225; rhodium, $195–$200; and ruthenium, $50–$55.

The dealers' prices for most of the platinum metals rose sharply during the year. After a brief decline from $113–$116 to $102–$105 in January, platinum rose to $155–$160 in August, declined to $137–$143 in September, rose again to $147–$149 in December, and dropped back to $139–$141 at yearend. The dealers' price for palladium declined from an initial $36–$37 to $30.50–$36 in the second quarter, then rose to $40.25–$42, and in August rose again to $60–$62. After a decline to $59–$61 in September through November, the price rose to $69–$72, and finished the year at $67–$68. Iridium began the year at $145–$148, jumped to $525 in early May on the strength of news about its use in a new catalytic product, then declined to $275–$300 at yearend. Ruthenium prices advanced from $45 to $58–$60 per ounce during the year. The dealers' price for osmium declined from $175–$200 to $150–$175; rhodium prices remained unchanged at $195–$198.

FOREIGN TRADE

Exports of platinum-group metals rose 33% in quantity and 55% in value compared with 1971 exports. Platinum exports alone rose 30% in quantity and 50% in value; platinum comprised about 77% of the total quantity and 85% of the total value of all platinum-group exports in 1972. Exports of other platinum-group metals rose 46% in quantity and 87% in value in 1972. Of all platinum-group metals exported, 91% went to five principal countries—Japan, West Germany, the United Kingdom, Belgium-Luxembourg, and Italy. The sharpest increase in exports was to Japan, the quantity rising from about 94,265 ounces in 1971 to 254,460 ounces in 1972. About 77% of the exports to Japan in 1972 consisted of unworked and partly worked but unrolled platinum metal. Exports to West Germany rose 33% in 1972; sharp declines were noted in exports to the United Kingdom and France.

U.S. imports of platinum-group metals rose 41% in quantity and 54% in value in 1972. Unwrought platinum and palladium imports rose 10% and 31%, respectively. Semimanufactured forms increased, platinum by 97% and palladium by 39%. Imports of all other platinum-group metals also rose sharply, with ruthenium more than doubling and iridium and rhodium up about 74% and 47%, respectively. About 91% of all imports came from four countries—the U.S.S.R., the United King-

r Revised.

[1] Less than ½ unit.

Note.—In addition, platinum content from materials n.e.s.: 1971, 85,170 troy ounces ($7,350,966); 1972, 45,229 troy ounces ($3,222,233); and platinum content from precious metal ores: 1971, 133 troy ounces ($19,262); 1972, 10,606 troy ounces ($952,980).

dom, the Republic of South Africa, and Japan. Imports from the U.S.S.R. were up 81% from those in 1971 and consisted mainly of palladium (67%) and platinum (20%) semimanufactures. Unwrought metals were also imported from the U.S.S.R. Imports of platinum-group metals from Japan were up nearly 5 times the 1971 quantities. Imports from the Republic of South Africa rose 43%, while those from the United Kingdom rose only 6%.

WORLD REVIEW

World production of platinum-group metals rose 13% in 1972, chiefly because of expansions in the Republic of South Africa and in the U.S.S.R. Platinum producers were buoyed by several large contracts to supply platinum metals to automobile manufacturers for exhaust control. Although contracts generally had some kind of escape clause to limit deliveries if metals were not needed, producers had adequate assurance to proceed with expansion plans. Most of the activity was in the area of the Merensky Reef, Republic of South Africa, and the Norilsk area, U.S.S.R. An estimated 80 to 90% of Soviet production continued to come from the Norilsk and Petsamo areas of the U.S.S.R., where copper and nickel ores contain a small fraction of an ounce per ton of platinum-group metals in the approximate following proportions: 30% platinum, 60% palladium, and the remaining 10% in ruthenium, rhodium, iridium, and osmium. Deposits in the Republic of South Africa, on the other hand, were estimated to contain the following proportions: 64% platinum, 24% palladium, 5% ruthenium, 4% rhodium, 2% iridium, and less than 1% osmium in ores generally averaging 0.15 ounce of platinum metals per ton. Nickel, copper, and a little gold were also present in the South African ores.

Philippine production contained in nickel-cobalt concentrate produced by Acoje Mining Co. at Santa Cruz, Zambales Province, Luzon, rose sharply in 1972 and totaled about 8,000 ounces, two-thirds of which was palladium. Concentrates were shipped to Japan for refining. Finland continued to produce byproduct platinum from the Outokumpu Oy copper smelter. The International Mining Corp. operated dredges in the Choco and Nariño districts of Colombia and produced about the same quantity of platinum as reported in 1971. Canadian production declined in 1972 owing to a cutback in nickel production because of oversupply. Most production came from the Sudbury district as a byproduct of nickel-copper operations of International Nickel Co. of Canada Ltd. and Falconbridge Nickel Mines Ltd. The bulk of the platinum was refined at Acton in the United Kingdom, and at Newark, N.J.

South Africa, Republic of.—South African production resumed its upward trend after dropping sharply in 1971 because of depressed markets. With the renewed assurance that platinum catalyst demands would greatly expand sales, producers had a variety of projects underway. Rustenburg Platinum Mines Ltd. and Impala Platinum Ltd. completed smelter and mine expansions begun in 1970 and planned additional improvements. Rustenburg's New Wadeville refinery to extract platinum-group metals from matte was scheduled for operation in 1974, and thereafter only a small portion of the matte product would be exported. Ore reserves of potential new mines in four areas held by Rustenburg's parent company, Johannesburg Consolidated Investment Co. Ltd. (JCI), were as follows: Swartkop, 300 million metric tons, 70–80% payable; Derbroken, 100 million tons, 70–80% payable; unnamed property on updip side of the Atok mine, 200 million tons, 30% payable; and Potgietersrust, 50 million tons (opencast). Reserves of other companies were generally adequate for planned expansions, although additional shafts and increased milling and refining capacities were expected to be required. Estimated mine capacities and production rates in 1972 were as follows, in thousand ounces:

Mine	Capacity (yearend)		Production	
	Platinum-group metals	Platinum	Platinum-group metals	Platinum
Rustenburg, including Union section	1,700	1,200	800	500
Impala (Bafokeng)	600	350	500	350
Western Plats (began in March 1971)	135	100	135	100
Atok	18	11	18	11
Total	2,453	1,661	1,453	961

The Merensky Reef platinum deposits and platinum processing in the Republic of South Africa were described.[11] Installed annual capacity of the industry was estimated at 1.5 million troy ounces of platinum and 1 million ounces of other platinum-group metals (mainly palladium). The largest of four active producers was Rustenburg Platinum Mines Ltd., with installed capacity of 1.7 million ounces and an expansion program underway. The main concentration of values in the Merensky Reef was confined to a persistent ¾-inch chromite-rich platiniferous band. Ores were concentrated at Waterval and Klipfontein and concentrates were smelted to matte at Waterval. Future production based on existing expansion plans in September 1972 was, as follows, in thousand ounces of platinum-group metals:

Mine	1973	1974	1975	1980
Rustenburg	1,700	2,000	2,200	3,000
Impala	600	850	950	1,500
Western Plats	185	235	285	500
Atok	18	40	290	350
Eland	--	(1)	300	475
Total	2,503	3,125	4,025	5,825

(1) Possibly some production in late 1974.

Labor shortages and limited local short-term financing loomed as problems to expanded production. It was estimated that 10,000 workers were needed per 300,000 ounces of platinum production. Competition with South African gold producers for labor was a factor. About 300 million South African rands ($360 million) in capital financing was estimated to be needed for each 1-million-ounce expansion over the 1972 production levels.

Marketing of South African production continued through established sales channels in Europe, Japan, and the United States. Output of Rustenburg Platinum

U.S.S.R.: Placer platinum and platinum-group metal recovered from platinum-nickel-copper ores [e]	2,200,000	2,300,000	2,350,000
United States: Crude placer platinum and byproduct metals recovered largely from domestic gold and copper refining	17,316	18,029	17,112
Total	4,238,956	4,084,110	4,613,431

[e] Estimate. [p] Preliminary.

[1] Excludes refined platinum production from Norway, which is derived from imported raw materials, chiefly (if not wholly) of Canadian origin, in order to avoid double counting.

Mines Ltd. was marketed by Johnson Matthey & Co. Ltd. and Engelhard Minerals & Chemicals Corp.; Impala Platinum Ltd. sold through Ayrton Metals Ltd.; Western Platinum Ltd. sales were handled by Falconbridge Nickel Mines Ltd.; and Atok Investments (Pty) Ltd's limited production was sold through the Anglo-Vaal Group. Stocks of platinum-group metals on hand in South Africa were estimated about 500,000 ounces in September 1972.

TECHNOLOGY

Interest in platinum technology in 1972 centered around development of viable catalytic exhaust emission systems for automobiles to enable new production models to meet the requirements of the Clean Air Act of 1970, as amended. Problems of configuration, support mechanisms, most effective and economic platinum metal compositions, durability and location of units with respect to other exhaust components were studied.[12] Generally, a composition of platinum and palladium on a ceramic honeycomb support structure was found to be effective and promising. General Motors Corp. reportedly was testing two dual catalytic systems, one of which would use a combination of 0.1 ounce of platinum and 0.04 ounce of palladium per automobile.[13] Ruthenium was also expected to be incorporated in smaller quantities. With the expected use of platinum catalytic devices will come increased demand for unleaded gasolines, because lead in existing fuels "poisons" the catalysts rendering the units ineffective. A consequence was that platinum metals would also be needed in greater quantities for reforming and other refining operations to increase gasoline extraction and octane ratings.

As in past years, Johnson, Matthey & Co. Ltd., of London, published its quarterly, Platinum Metals Review, describing research and developments in the platinum metals. Among the more interesting reports in 1972 were those on "High Pressure Research on Palladium-Hydrogen Systems" (January, pp. 10–15), "Platinum Catalysts in Lead-Free Gasoline Production" (April, pp. 42–47), "Automobile Emission Control Systems" (July, pp. 74–86), and a review of the "Fifth International Congress on Catalysis" (October, pp. 138–139). Unique catalytic properties were noted when platinum metal halides were reacted with aromatic radical-ions such as sodium napthalide and related species in a study of the products of such reactions.[14] As an example, platinum prepared in this way could be dissolved readily in hot 68% nitric acid. Outstanding activity was shown by the platinum-group metals as catalysts in the oxidation of organic compounds by molecular oxygen. Electrostatic and magnetic susceptibility properties were also changed.

Occurrence and distribution of platinum, palladium, and rhodium in the Stillwater Complex of Montana was described.[15] Values generally were too low to have economic significance. Existence of a platinum indicator flower, identified as Eritrichium chamissonis, was reported in Alaska after a study of its association with ultrabasic rocks on Red Mountain, believed to be the source of platinum deposits in Goodnews Bay, Alaska.[16] The flower was found to be a useful prospecting guide to the soil overlying deposits. These soils were favored by the plant owing to release of leachable cations in the process of weathering, but the plant itself did not appear to take up platinum.

Platinum-group metals were recovered with other precious metals from electronic scrap in experiments conducted by the Bureau of Mines at its Salt Lake City Metallurgy Research Center[17] and its Boulder City Metallurgy Research Laboratory.[18]

Potash

By Donald E. Eilertsen [1]

Moderate production, higher prices, record consumption and imports, and unusually large exports were some of the highlights of marketable potassium salts in the United States in 1972. Imports of potash were larger than domestic production for the second consecutive year. The Province of Saskatchewan, Canada, continued its production and pricing regulations for the third consecutive year. These regulations have been largely responsible for higher worldwide potassium muriate prices since the low prices of 1969.

Table 1.—Salient statistics on potassium salts

(Thousand short tons and thousand dollars)

Item	1968	1969	1970	1971	1972

[1] Excludes potassium chemicals and mixed fertilizers.
[2] Measured by sold or used plus imports minus exports.

DOMESTIC PRODUCTION

Domestic production of marketable potassium salts consisting of potassium chlorides (muriates), potassium-magnesium sulfate, potassium sulfate, and mine-run salts in terms of potassium monoxide (K_2O) equivalent was 2.8% larger than in 1971. Production has ranged from 2.6 to 2.8 million tons of K_2O annually since 1968; record production of 3.3 million tons of K_2O production occurred in 1966. Eleven producers in three States produced marketable potassium salts in 1972. The companies were AMAX Chemical Corp., Duval Corp., International Minerals & Chemical Corp. (IMC), Kerr-McGee Corp., National Potash Co., Potash Co. of America, Division of Ideal Basic Industries, Inc., and Teledyne Potash (formerly United States Potash & Chemical Co.) all in New Mexico; Great Salt Lake Minerals & Chemicals Corp., Kaiser Aluminum & Chemical Corp., and Texas Gulf, Inc. (formerly Texas Gulf Sulphur Co.) in Utah; and Kerr-McGee Corp. (American Potash Division), in California.

New Mexico accounted for 86.3% of the national production of marketable K_2O in 1972. The average grade of mined ore declined from 17.3% K_2O in 1971 to 16.3% K_2O in 1972, the lowest in many years.

[1] Sylvite and langbeinite.
[2] Derived from reported value of "Sold or used."
[3] Data may not add to totals shown because of independent rounding.

Potash producers in the United States had about 3.5 million tons of K_2O plant capacity in 1972 of which New Mexico accounted for approximately 2.8 million tons. Based on these figures, the potash industry of the United States operated at 76.5% capacity in 1972, and New Mexico producers operated at 82.4% capacity. The United States consumes much more potash than it has plant capacity. Consequently, large quantities of potash are imported to meet demand.

Texas Gulf, Inc., resumed potassium chloride production at its Cane Creek operation at Potash, Utah, in March after converting from underground mechanized mining to a combination of solution mining and solar evaporation. The mixed salts, consisting of potassium and sodium chlorides, are separated in the company's original refinery. This is the first potash solution mining operation in the United States; the only other similar operation is in Saskatchewan, Canada.

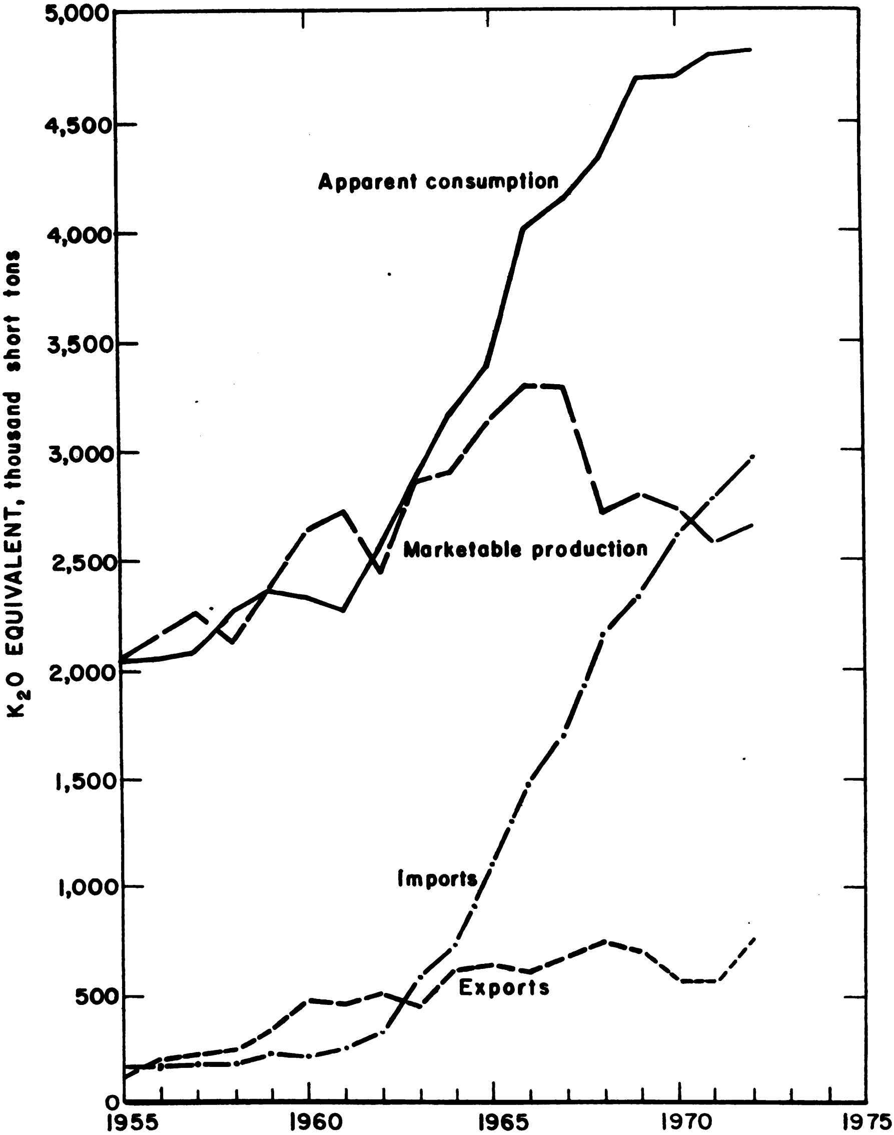

Figure 1.—Marketable production, apparent consumption, exports, and imports of potassium salts measured in K_2O equivalent.

Searles Lake Chemical Corp., a subsidiary of Occidental Petroleum Corp., continued preparations to extract potassium sulfate, borax products, and soda ash from brines at Searles Lake, Calif.

Approximately 178,000 tons of liquid potassium hydroxide, caustic potash, 88% to 92% pure, was produced from chemical-grade potassium muriate in the United States in 1972.

CONSUMPTION AND USES

Apparent consumption of 8.27 million tons of potassium salts (4.81 million tons of K_2O), measured by sales plus imports minus exports, continued the trend of establishing new records. The United States, as usual, continued to be the world's largest consumer of potash.

According to the Potash Institute of North America, deliveries of domestic and imported potassium salts for agricultural and chemical purposes in the United States were 4.65 million tons of K_2O equivalent. Of this quantity, 4.38 million tons of K_2O (94.2%) was agricultural potash, and 0.27 million tons (5.8%) was chemical potash. Illinois, Iowa, Indiana, Minnesota, and Ohio were the largest recipients of potash for agriculture, and together accounted for 38.2% of this total. New York, Illinois, Alabama, Delaware, and Kentucky accounted for 72.4% of the potash delivered for chemicals.

A large use for chemical-grade potassium chloride is as raw material for producing electrolytic potassium hydroxide (caustic potash) and byproduct chlorine. Caustic potash has direct applications and also large usage as starting material for producing many other chemicals for a variety of uses.

STOCKS

At yearend, producers' stocks totaled 881,000 tons of marketable potassium salts containing 469,000 tons of K_2O equivalent —9.6% more K_2O than in 1971. Yearend stocks of imported potassium salts were not available.

Table 5.—Yearend stocks of marketable potassium salts in the United States

(Thousand short tons)

Year	Number of producers	Stocks, Dec. 31	
		Gross weight	K_2O equivalent
1968	13	1,175	676
1969	12	723	392
1970	13	875	454
1971	11	796	428
1972	11	881	469

TRANSPORTATION

Freight rates were obtained for shipments of muriate of potash (KCl) from points of origin in the United States and Canada to various destinations in the United States. One analysis, based on a minimum weight of 40 tons of KCl per car (table 6), indicated that U.S. producers would have a shipping cost advantage and could ship KCl at lower freight rates from their plants to points south of a zigzag line extending from the northeastern corner of Idaho, to Billings, Mont., North Platte, Nebr., Des Moines, Iowa, St. Louis, Mo., Madison, Wis., Chicago, Ill., Indianapolis, Ind., Lansing, Mich., Columbus, Ohio, Harrisburg, Pa., Richmond, Va., Baltimore, Md., Syracuse, N.Y., and Concord, N.H.; whereas Canadian producers would have the advantage in shipping to points north of the same line.

Another analysis indicated that New Mexico producers could ship KCl advantageously to points south of a zigzag line extending from Seattle, Wash., to Portland, Oreg., Pocatello, Idaho, a point a few miles north of Casper, Wyo., then to North Platte, Nebr., Des Moines, Iowa, Madison, Wis., Chicago, Ill., Lansing, Mich., Indianapolis, Ind., Columbus, Ohio, Richmond, Va., Baltimore, Md., Harrisburg, Pa., Syracuse, N.Y., and Concord, N.H. For several destinations, the freight rates were lower for larger minimum weights per car. Canadian producers would have the lower rates for KCl shipped to points north of this line.

The study also revealed that considerable KCl is transported by rail and truck from certain Saskatchewan producers to Northgate, N. Dak., for reshipment by train to various destinations in the United States. For a minimum weight of 40 tons per car, the freight rate to Northgate from Saskatchewan was quoted at $16.05 per ton. However, for minimum weights of 50 tons in box cars or 60 tons in covered hopper cars, the rate was $14.77 per ton. Large tonnages of potassium muriate from Saskatchewan were reportedly transported

Table 6.—Freight rates per short ton of muriate of potash (KCl) from producing centers to various destinations, minimum weight 40 short tons of KCl per car

by truck to Northgate, for about $4.75 per ton.

From Northgate, the KCl is transported by unit trainloads weighing at least 10,000 tons to Minneapolis and St. Paul, Minn., and Allovez, Wis., at $4.23 per ton; to Albert Lea, Minn., and Manly, Iowa, at $4.74 per ton; to Mendota and Beardstown, Ill., at $6.01 per ton; to Menon and Sheridan, Ind., at $6.83 per ton; and to Bellefontaine and Columbus, Ohio, at $7.77 per ton.[2] These low rates are obtainable only when the total tonnage from all shippers amounts to 200,000 tons during January to June, or 220,000 tons during July to December.

PRICES

Standard domestic potassium muriate (KCl), f.o.b. refineries, had an average sales value of $20.22 per ton in 1972 compared with $19.27 per ton of KCl in 1971. The average sales value of coarse KCl was $21.58 per ton compared with $21.50 per ton in 1971. The average sales value of granular KCl was $22.09 per ton in 1972 compared with $22.84 per ton in 1971.

The average sales value of domestic potassium sulfate at refineries was $41.76 per ton compared with $36.43 per ton in 1971.

The average value of U.S. imports for consumption of all types of potassium muriate from Canada was $22.97 per ton of KCl at Canadian points of exportation compared with $23.18 per ton in 1971.

Higher prices since 1970 have been largely attributed to existence of the Province of Saskatchewan's Potash Conservation Regulations.

Quoted prices on various New Mexico and Saskatchewan potash materials are shown in table 7.

In Phase II of the President's economic stabilization controls, effective November 1971, the Price Commission permitted potash producers to continue using seasonal fluctuations of prices for their products.

FOREIGN TRADE

Exports and imports of potash fertilizer and chemical materials are shown in tables 8–9.

Exports of 1.35 million tons of potassium salts (764,000 tons of K_2O) were unusually large. Of these salts, 1.13 million tons were potassium chloride.

Imports for consumption of potash materials are shown in tables 10–11. Imports for consumption of 4.97 million tons of potassium salts (2.96 million tons of K_2O) broke all records and were larger than domestic production for the second consecutive year. A total of 4.64 million tons of potassium chloride (about 2.8 million tons of K_2O) valued at $106.5 million was imported from Canada in 1972 compared with 4.4 million tons of potassium chloride (2.7 million tons of K_2O) valued at $102.9 million in 1971.

Shipments (awards) of various domestic fertilizer materials financed by the Agency for International Development (AID) in 1972 included 5,512 short tons of potassium chloride and potassium sulfate ($328,958) to South Vietnam. In 1971, AID-financed shipments of various domestic fertilizer materials included 4,850 tons of potassium chloride ($240,988), 8,047 tons of potassium sulfate ($528,995), and 772 tons of sulfate of potash magnesia ($33,355) to South Vietnam, 3,858 tons of potassium chloride ($103,600) to Colombia, and 4,985 tons of potassium sulfate ($257,834) to Nigeria and Morocco.

WORLD REVIEW

World production of marketable potash continued at a high level in 1972 as shown in table 12. According to preliminary estimates, the United States was the fourth largest producer. In slightly over a decade, Canada emerged from a nonproducer of potash to the country with the world's largest potash capacity, 8.3 million tons of K_2O annually. The potash operations are all in Saskatchewan. The Province continued to regulate its huge potash industry with production and minimum price controls for the third consecutive year; the facilities operated at about 52% capacity in 1972.

The Saskatchewan Potash Conservation Regulations have been acclaimed by some producers as an outstanding success.[3] A detailed review of the regulations was published.[4]

e Estimate. p Preliminary. r Revised.

Australia.—Texada Mines Pty., Ltd., reportedly began construction of an 88,000 short-ton potash plant costing $4.5 million at Lake McLeod, north of Carnarvon, Western Australia. The plant will produce potash from brine and is expected to come onstream in May 1973. The facility can be easily enlarged to produce 154,000 short tons of potash annually and, if the demand is brisk, expanded to produce 309,000 short tons annually.[5]

Canada.—Cominco, Ltd., resumed sylvinite mining operations at Vade, Saskatchewan, in September after being shut down since August 1970 as the result of a mine flood.[6]

Saskatchewan potash producers organized Canpotex, Ltd., to develop larger offshore markets for their potassium chlorides.

American Metal Climax, Inc., made an agreement in 1971 with IMC (Canada) to purchase some of IMC's potash reserves in Saskatchewan for producing potassium muriate through IMC's facilities.

Potash Co. of America, Division of Ideal Basic Industries, Inc., signed an agreement with the Province of New Brunswick giving the company the sole right to explore the new potash deposits in the Sussex area. The deposits are near the deepwater port of Saint John. The agreement also gave the company first option to develop the deposits commercially.[7]

China, Peoples Republic of.—Potassium chloride and various other byproducts are produced during the treatment of lake salt in Tsinghai.

Israel.—A new potassium nitrate plant with a capacity of 120,000 short tons per year reportedly operated at full capacity. Potassium chloride originating in Israel is reacted with nitric acid in aqueous isoamyl alcohol yielding potassium nitrate. The nitrate is removed and further treated for marketing.[8]

U.S.S.R.—The Soviet Union has eight potash facilities consisting of mines and refineries. Of these, three in the Urals and three in Belorussia produce potassium chloride, and two in the Ukraine produce potassium-magnesium sulfate and potassium sulfate.

Room-and-pillar methods of mining are used, and trends are for larger recoveries and greater mechanization. Approximately 120 mechanical miners were used in 1970 to produce about 13 million short tons of ore.

Beneficiation methods in use are about the same as those used elsewhere in the world. However, most of the ores contain several potash minerals and often large amounts of clay. Research on the ores include developing methods for the removal of clay and developing electrostatic beneficiation methods for the direct production of potash products and also for improving ores for flotation.[9]

TECHNOLOGY

Sylvite of Canada's new potash mine near Rocanville, Saskatchewan, is one of the most highly mechanized and automated mining operations in the world. On a 10-hour shift, a supervisor and seven-man crew of operators can produce over 600 tons of sylvite ore per hour. Two four-rotor, 258-ton Marietta mining machines are used for extracting the ore. General plans are for 35% extraction of a 4,000 feet square panel using room-and-pillar methods of mining with rooms parallel and 67 feet wide. The ore deposit is about 3,000 feet below surface and has been described as a gently undulating flat blanket of ore 8 feet thick extending many miles in all directions. The compressive and tensile strengths of the ore are roughly 3,000 pounds per square inch and 500 pounds per square inch, respectively. The hoisting of ore to surface is highly automated; electric power peaks are controlled by varying skip loads of 24 and 15 tons and speeds of 1,000 or 1,800 feet per minute. The operation of all mining equipment and facilities from the working face to storage bins in the headframe on surface is monitored and controled from a single central control panel in the mine.[10]

The highly mechanized potash mining operations of Alwinsal Potash of Canada, Ltd., 8 miles west of Lanigan, Saskatchewan, were described.[11] The Dreyer Formula was used in calculating room-and-pillar dimensions. Rooms are 28 feet wide, pillars 59 feet wide and 146 feet long; panel extraction is 38.5%. With more experience, plans might be changed. Additional crosscutting may be done leaving 59-foot-square pillars. If this is done, ore extraction would be 47%, and the pillar safety factor would be 3. The average grade of mined ore is 25% K_2O, and the company's reserves are estimated at over 100 million tons of K_2O. Skip loads of ore weighing 22.5 tons are hoisted from a depth of 3,250 feet to surface at a speed of 3,600 feet per minute.

Ten years of scientific studies in Saskatchewan's deep potash mines revealed that all mine roof failures follow two basic patterns: mass failure—caused by the weight of overburden, and slab buckling—caused by weak discontinuity planes in the ground. An effective stress control method was developed for stabilizing underground openings based on accurate in situ stress analysis. The success of the new method is largely due to the development of the Rheological Element Computer Control Method and use of a portable in situ stress meter. Some advantages of using the stress control method are as follows: the development of wider rooms such as those Sylvite of Canada plans to use, complete or partial elimination of roof bolting, increased production efficiency, and better control of ventilation and subsidence.[12]

Pumice and Volcanic Cinder

By Arthur C. Meisinger [1]

The quantity of pumice, pumicite, and volcanic cinder sold or used by producers and the quantity of pumice imported for consumption to meet the increased demand for pumiceous materials in construction-related uses set record highs in 1972. Domestic production was 3.8 million tons valued at $6.5 million from 220 operations in 16 States. Pumice imports in 1972 totaled nearly 600,000 tons valued at a record $1.5 million.

DOMESTIC PRODUCTION

Domestic production of pumiceous materials in 1972 was 12% higher in quantity and 25% higher in value than in 1971. The quantity produced in 1972 was 3.8 million tons, a record total. The previous high was established in 1969 when production of pumice, pumicite, and volcanic cinder amounted to 3.6 million tons. The value of 1972 output was $6.54 million, which was the highest since 1966. Volcanic cinder, ash, and scoria comprised 79% of the U.S. output of pumiceous materials and was valued at a record $4.66 million.

Domestic output in 1972 came from 101 firms, individuals, and governmental agencies producing from 220 operations in 16 States. The principal producing States, in order of output, were Oregon, Arizona, and California, and their combined output accounted for two-thirds of the national total. Other States with significant output were Hawaii, Nevada, and New Mexico. Of the six leading States, only Arizona and Oregon showed a decrease in production from that of 1971. California led all producing States with 95 active operations, followed by Arizona with 34, and Hawaii with 22. Volcanic cinder was produced in 13 of the 16 States and in American Samoa from a mine operated by the Samoan Government.

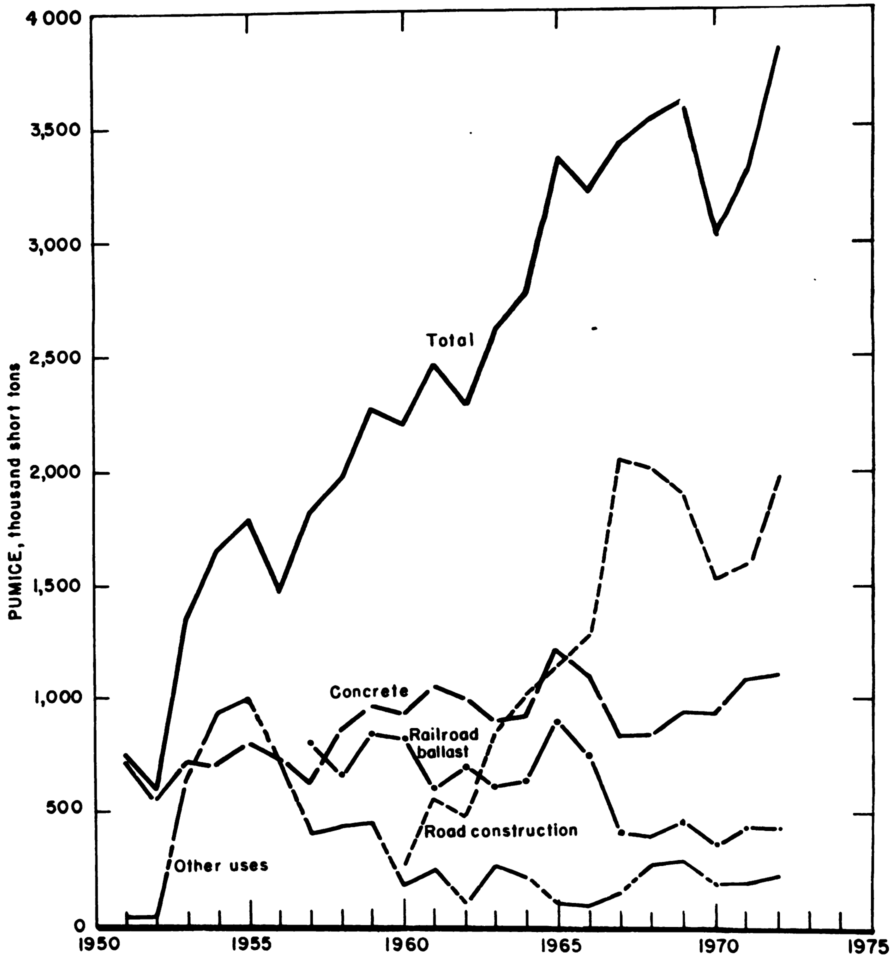

Figure 1.—Pumice and volcanic cinder sold or used by producers in the United States, by use.

CONSUMPTION AND USES

Road construction (including ice control and maintenance) and concrete admixture and aggregate, the principal end uses of pumiceous materials, accounted for 52% and 31%, respectively, of U.S. consumption of pumice and volcanic cinder in 1972. Of the remaining 17%, railroad ballast made up 11% and abrasive materials and other uses, 6%. Landscaping and roofing, combined, accounted for three-fourths of the 212,000 tons of pumice and volcanic cinder included under "other uses" in table 3.

Compared with consumption in 1971, use in road construction increased 18%; use in concrete admixture and aggregate, 11%; and other uses, 9%. On the other hand, use as abrasive materials in cleaning and scouring compounds decreased 25% compared with that of 1971, but use in railroad ballast declined only 1%.

Table 3.—Pumice, pumicite, and volcanic cinder sold or used by producers in the United States, by use

PRICES

The average value for crude pumice, pumicite, and volcanic cinder sold and used decreased from $1.07 per ton in 1971 to $0.98 per ton in 1972. Prepared pumice, pumicite, and volcanic cinder, however, increased in average value from $2.20 per ton in 1971 to $2.42 per ton. The weighted average value of pumice, pumicite, and volcanic cinder sold and used was $1.71 per ton compared with $1.54 per ton the previous year. The weighted average value increase of $0.17 was due in large part to rising milling costs and greater demand for prepared material.

The average 1972 price per ton for pumice and volcanic cinder (scoria) used in cleaning and scouring compounds was $9.86, an increase of $7.04 from the 1971 price; for concrete admixture and aggregate, $2.01, a $0.03 increase; for railroad ballast, $0.93, a $0.27 increase; for road construction, $1.18, a $0.04 increase; and for other uses, including landscaping and roofing, $5.78, a $1.61 increase.

Price quotations for pumice in Chemical Marketing Reporter (formerly Oil, Paint, and Drug Reporter) remained unchanged from 1971 and were as follows per pound, bagged, in ton lots: Domestic, fine, $0.0460 to $0.0487; domestic, medium, $0.0510; domestic, coarse, $0.0460; imported (Italian), silk-screened, coarse, $0.06 to $0.076; imported, fine, $0.05; and imported (Italian), sun-dried, fine and coarse, $91 per ton.

Prices quoted at yearend in the American Paint Journal also remained unchanged from 1971, and were as follows for pumice stone per pound, in barrels, f.o.b. New York or Chicago: Powdered $0.0445 to $0.08, and lump $0.0665 to $0.09.

FOREIGN TRADE

The quantity of pumice exported in 1972 was 28% lower than in 1971, and the value was also lower by 33%. Of the 256 short tons exported to 12 countries, Canada received 65% of the exports.

Pumice imported for consumption set a record in 1972, in both quantity and value. Nearly 600,000 short tons was imported, of which 98% was obtained from Greece and Italy, to meet the growing demand for pumice used in the manufacture of concrete masonry products. Total value of all import classes of pumice was $1.5 million compared with $1.1 million in 1971. Imported pumice used in the manufacture of concrete masonry products increased 51% from 388,312 tons in 1971 to 587,269 tons, and imports classed as crude or unmanufactured increased 3% from 8,833 tons to 9,094 tons in 1972. Imports classed as wholly or partly manufactured, however, decreased 4% from 2,588 tons in 1971 to 2,489 tons.

Pumice stone, TSUS No. 519.05, for use in concrete products continued to be admitted into the United States duty free. Duties for other pumice products were as follows: TSUS No. 519.11, crude or crushed pumice, valued not over $15 per ton, 0.02 cent per pound; TSUS No. 519.14, crude or crushed pumice, valued over $15 per ton, 0.04 cent per pound; TSUS No. 519.31, grains or ground, pulverized or refined, 0.17 cent per pound; and TSUS Nos. 519.93 and 523.61, millstones, abrasive wheels, and abrasive articles n.s.p.f. and articles, n.s.p.f., 7% ad valorem.

Rare-Earth Minerals and Metals

By James S. Kennedy [1] and James H. Jolly [2]

The rare-earth industry in 1972 was highlighted by planned expansion of production facilities, increased demand for rare-earth products, changes in demand patterns, and promising technological developments.

The Molybdenum Corp. of America (Molycorp) announced plans to expand its bastnaesite mill at Mountain Pass, Calif. Titanium Enterprise's facilities for production of byproduct monazite near Green Cove Springs, Fla., were completed and went on stream late in the year. Shipments from rare-earth chemical processors increased and, for the first time in the history of the industry, metallurgical consumption surpassed that of the petroleum industry as the largest market for rare-earth products. The growing metallurgical demand for mischmetal prompted the Aluminum Co. of America (Alcoa) to enter the industry in a joint venture with Molycorp.

Worldwide, Australia, India, Brazil, and Malaysia remained the leading producers of monazite concentrates. Export destinations of the Australian material changed markedly during the year. Production of rare-earth compounds and metals appeared adequate to meet market demand although mischmetal was reported in short supply in the United Kingdom. Mischmetal producers in Western Europe were reportedly prepared to expand capacity, estimated at 1,500 tons per year, in order to meet growing market requirements.

Legislation and Government Programs.—At the end of 1972, the General Services Administration (GSA) held a total of 11,817 short tons (dry) of rare earth oxide (REO) equivalent in the national (9,714 tons) and supplemental (2,103 tons) stockpiles, compared with 11,841 tons at the end of 1971. Although 1,250 tons of REO content was authorized for disposal in 1972, less than 27 tons of REO contained in bastnaesite was sold during the year. In addition several test samples of rare-earth chloride from the stockpile were provided to industry.

DOMESTIC PRODUCTION

Concentrate.—The Mountain Pass, Calif., operation of Molycorp produced 11,802 tons of REO in flotation concentrate from 228,488 tons of bastnaesite ore mined and milled. Production was sluggish at the beginning of the year but was near capacity during the fourth quarter. In anticipation of increased demand, a $850,000 expansion program was announced in January 1973, to increase mill and flotation capacity by 50% to 30,000 tons REO annually. The new facilities are expected to be on stream in August 1973.[3]

Molycorp acquired options on several tracts of land in Johnson and Pawnee Counties in southeastern Nebraska, where test drilling in the Elk Creek carbonatite showed the presence of rare-earth minerals, among others. Analysis of the test hole drilled in 1971 by a survey team from the University of Nebraska, with support from the Bureau of Mines, revealed the presence of up to 1.1% cerium, 0.34% lanthanum, and traces of europium.[4]

Humphreys Mining Co. continued recovery of byproduct monazite from a beach sand deposit controlled by E. I. du Pont de Nemours & Co., near Folkston, Georgia.

Production declined slightly from that of 1971. As a result of its land reclamation program, Humphreys Mining Co. was presented the State of Georgia's first honor award for outstanding reclamation achievement.[5]

Titanium Enterprises, owned jointly by American Cyanamid Co. and Union Camp Corp., became a second producer of domestic monazite late in the year. The monazite produced is a byproduct in mining beach sand for titanium and zirconium minerals near Green Cove Springs, Fla.

Compounds and Metals.—Production of rare-earth compounds at the Louviers, Colo., Washington, Pa., and York, Pa., plants of Molycorp increased 24% in terms of contained REO; the value of production increased proportionally. The solvent extraction unit at Louviers includes facilities for production of selected high-purity oxides, including yttrium and europium.

Other major rare-earth chemical processors included Lindsay Rare Earths Division of Kerr-McGee Chemical Corp., West Chicago, Ill., and W. R. Grace & Co., Davison Chemical Div., Chattanooga, Tenn.

Smaller producers of rare-earth com-

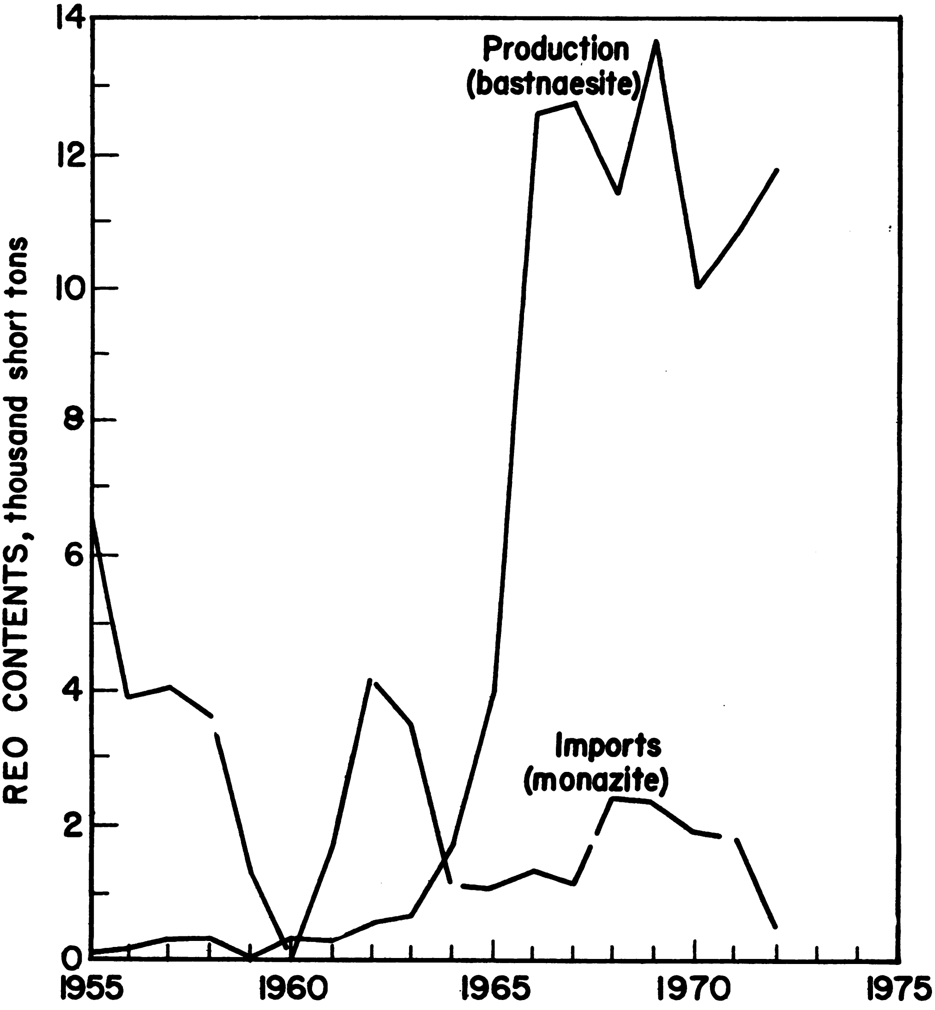

Figure 1.—Domestic production of bastnaesite and imports of monazite.

---

[5] Engineering and Mining Journal. V. 173, No. 9, September 1972, p. 197.

pounds and metals were: Atomergic Chemetals Co., Div. of Gallard-Schlesinger Chemical Manufacturing Corp., Carle Place, N.Y.; Michigan Chemical Corp., St. Louis, Mich.; Research Chemicals Div., Nucor Corp. (formerly Nuclear Corp. of America), Phoenix, Ariz.; and Transelco, Inc., Penn Yan, N.Y. Molycorp, W. R. Grace, Kerr-McGee, Michigan Chemical, Gallard-Schlesinger, and Nucor produced yttrium oxide and metal during the year.

Production of mischmetal and other pyrophoric alloys, limited to Ronson Metals Corp. and American Metallurgical Products Co., Inc. (Amet) increased 16% while shipments rose 41% over those of 1971. Reaction Metals Inc., a subsidiary of Rare Earth Industries, Inc., Orlando, Fla., acquired Amet's mischmetal plant at Newcastle, Pa., during the year. Amet will continue as marketing representatives for rare-earth additives produced for the steel industry.[6]

Electralloy Corp., Oil City, Pa., began experimental production of a REO containing deoxidation alloy for use in the steel industry. Full production was planned for 1973.

Formation of Rare Earth Metals Co. of America (Remcoa), a joint venture of Alcoa (51%) and Molycorp (49%), was announced.[7] A pilot plant for evaluation and modification of an electrolytic reduction process developed by the Bureau of Mines Metallurgy Research Center, Reno, Nev.,[8] is to be installed at Molycorp's Washington, Pa., facility. Plans include construction of a plant with an annual capacity of 500,000 pounds, scheduled for completion by 1974. Production will be limited to mischmetal, rare-earth metals, and rare-earth alloys.

CONSUMPTION AND USES

Domestic rare-earth processors consumed an estimated 16,100 tons of REO contained in raw material during 1972. Bastnaesite consumption more than doubled while consumption of monazite declined almost 10%. Consumption of monazite by W. R. Grace at Chattanooga, Tenn., increased more than 28%.

Shipments of rare-earth products from principal processing plants to domestic consumers totaled about 9,400 tons REO, valued at $18 million. This quantity includes intracompany shipments by Molycorp, but does not include products derived from further processing at its plants in Pennsylvania and Colorado. The following estimated quantitative percent distribution of rare-earth products usage during 1972 is based on information supplied by primary processors and on actual data from certain consumers: Metallurgical, including nodular iron and steel, other alloys, and lighter flints, 44%; petroleum cracking catalysts, 33%; ceramics and glass, 17%; arc light carbons, 4%; and miscellaneous, including research and development, 2%.

The manufacture of petroleum cracking catalysts containing rare-earth zeolite as the active compound, continued at previous levels. However, this use declined as a percent of total consumption, being replaced by metallurgical applications as the largest consumer of rare-earth products. The impetus for the growth in metallurgical applications resulted in part from demand for large-diameter pipe to be used for the transportation of petroleum products. Rigid physical properties are required for this pipe to withstand the internal pressure and cold of areas such as the Arctic region. Rare-earth silicides, or mischmetal, added to high-strength low-alloy (HSLA) steels, at a rate of about 3 pounds per ton, to replace other additives such as manganese, form refractory sulfides which do not soften or elongate in applications which require rolling or stretching into shape. In addition to pipe, these steels are being used for the production of stronger auto bumpers. The use of rare-earth products in iron and steel was discussed.[9]

The use of low-cost cerium concentrate in glass decolorizing expanded and was primarily responsible for increased consumption of rare-earth products in ceramics and glass. A decolorization process was described.[10]

Interest in high energy permanent magnets, containing samarium alloyed with cobalt, continued strong with expanding demand. Varian Associates and Hamilton Precision Metals Co. announced commercial production of samarium-cobalt magnets in 1972. Applications are restricted to those uses that can take full advantage of their high energy density, such as aircraft and spacecraft motors and instruments, hearing aids, electronic tubes, and electric watches.

A new copper-base brazing alloy, containing lanthanum, was introduced during the year.[11] The addition of lanthanum enhances weldability and provides gettering and grain refining action. Available in powder or tape form, the alloy is applicable in joining different base metals from thin foils to thick sections and is suitable for wide gap brazing. Cost savings are possible because the alloy replaces more expensive gold or silver alloys in many applications.

In addition to its well-established use as a host material in color television phosphors, in the form of high-purity oxide, yttrium has various other applications. Cubic crystals of yttrium-aluminum-garnet (YAG) are substituted for diamonds in jewelry due to their high refractory index, hardness, and transparency. Neodymium-doped YAG lasers appear to be gaining wider acceptance in materials processing applications, such as hole drilling, welding, cutting operations, and scribing. Other uses for yttrium include high-temperature alloys and superalloys in such applications as turbine blades and vanes and are being considered for automobile thermal reactors.

STOCKS

Bastnaesite concentrate stocks held by the principal producer and five other chemical processors at yearend declined 10%; monazite concentrate stocks held by two chemical processing companies, however, declined 58%. Stocks of yttrium oxide and europium oxide held by four companies increased slightly. Mischmetal stocks held by two principal producers increased threefold, returning to levels maintained in the late 1960's. High-purity metals held by five firms were 71% lower at yearend than at the first of the year.

PRICES

Prices for domestic monazite remained stable during the year. On the London market the average c.i.f. price per metric ton of Australian monazite with a minimum of 60% REO plus ThO_2, quoted in Metal Bulletin (London) remained at $187 to $206 throughout the year. Malaysian xenotime concentrate with a minimum of 25% yttrium oxide as quoted in Industrial Minerals (London) remained unchanged at $3 to $5 per pound.

Unleached, leached, and calcined bastnaesite containing 55% to 60%, 68% to 72%, and 85% to 90% REO remained at 30, 35, and 40 cents per pound of REO, respectively, f.o.b. Mountain Pass or Nipton, Calif., in 100-pound paper bags or 55-gallon steel drums in truckload or carload lots.

Quoted prices per pound, f.o.b. plant, on certain rare-earth compounds were as follows: mixed rare-earth oxides, 97% REO, $1.40 for 500-pound lots decreasing to $1.10 for lots over 5 tons; chlorides, $0.29; carbonates, $0.83; fluorides, $0.90; and hydrates, $1.30. Quoted prices on cerium hydrate were stable for the year ranging from $1.30 to $1.60 per pound depending on purity and REO content; prices for polish-

[3] Minimum 1 pound.

---

[11] Metal Bulletin. No. 5765, Jan. 9, 1973, p. 12.

ing grade cerium oxide ranged from $1.20 to $2.00 per pound in 50-pound lots depending on quality and purpose; optical grade cerium oxide remained at $1.85 to $1.90 in lots of 50 pounds or more.

Quoted prices on 1-pound ingots in 50- to 100-pound lots of 97% didymium metal and cerium-free mischmetal remained at $15 and $5, respectively, f.o.b. plant. Mischmetal, 99.8%, was quoted at $3.10 per pound, same basis. Rare-earth silicide, 30% to 35% REO, was quoted at $1.50 to $1.56 per pound contained rare-earth metal, in lots of 15 tons or more.

Cerium metal, 99% pure, delivered in the United Kingdom as quoted in the Mining Journal (London) remained at $16.80 per pound, nominal.

FOREIGN TRADE

According to the sole domestic producer, Molycorp, exports of bastnaesite concentrate remained at the 1971 level of 2,500 tons contained REO. According to Bureau of the Census data, exports of ferrocerium and other pyrophoric alloys to France, Italy, Canada, and 18 other countries increased more than 236% to 202,206 pounds, valued at $609,678. The unit value ranged from $0.26 (Netherlands Antilles) to $7.23 (Australia) and averaged $3.02, compared with $2.72 in 1971. Exports of compounds and mixtures of rare-earth metals, yttrium, and scandium, increased from 763,951 pounds, valued at $1,480,116 in 1971 to 1,514,605 pounds valued at $3,143,895 in 1972, due primarily to the shipment of 799,480 pounds, valued at $191,875, to Austria. The increase in value was due to larger shipments of higher value material to Italy, Canada, and West Germany.

Imports of monazite sand declined substantially from the previous year. Shipments from Malaysia were reduced by 43% and, for the first year since the early 1960's, there were no monazite imports from Australia.

Cerium oxide imports from France and Switzerland totaled 9,219 pounds, valued at $23,342. Imports of cerium chloride increased substantially due to Canadian shipments of 2,556 pounds, valued at $1,534. Austrian shipments declined to 685 pounds, valued at $991. Other cerium imports from five countries, primarily France and the Netherlands, totaled 6,354 pounds, valued at $12,981.

Imports of rare-earth metals increased sharply during the year, although the value of the Japanese material declined considerably. Imports of ferrocerium and other pyrophoric alloys increased to 27,870 pounds valued at $94,347. Japan supplied 23,938 pounds, valued at $77,402, followed by West Germany, the United Kingdom, Austria, Taiwan, and France. The decrease in unit value, from $5.08 to $3.39, was due to the lower value of the Japanese material. Imports of mischmetal from West Germany declined from 52,204 pounds in 1971 to 22,118 pounds in 1972; there were no mischmetal imports from the United Kingdom in 1972.

Under the General Agreement on Tariffs and Trade ("Kennedy round") the tariff on cerium chloride and oxide was reduced on January 1, 1972, to 15% ad valorem. The rate for alloys of rare-earth metals and mischmetal was reduced to 50 cents per pound while the rate for ferrocerium and other pyrophoric alloys was reduced to 50 cents per pound plus 6% ad valorem.

WORLD REVIEW

Australia.—A pilot plant for evaluating methods of extracting rare-earths as a byproduct of uranium production was constructed at the Mary Kathleen mine, Queensland. Reconditioning of mine and mill facilities, currently on a care and maintenance status, is planned to begin in 1973 with production scheduled for late 1974.[12]

Canada.—Denison Mines, Ltd., announced plans to resume production of yttrium oxide early in 1973, according to the firm's 1972 annual report. Production ceased in mid-1970 after difficulties were encountered in marketing the product.

Finland.—Production of lanthanide concentrate at the Korsnäs lead mine of Outokumpu Oy was discontinued in 1971 due to lack of demand. Typpi Oy, which produced rare-earth compounds from concentrates formerly supplied by Outokumpu Oy, merged into another company, Kemira Oy.

Germany, West.—Goldschmidt A.G. terminated production of all rare-earth products (including europium oxide) except mischmetal and rare-earth metals and alloys for use in rare-earth magnets. Higher prices for rare earths were reported as a result of requirements to reduce air pollution.

India.—According to the annual report of Indian Rare Earths, Ltd. (IRE) for the year ending March 31, 1972, production of monazite increased to 4,664 tons from 4,004 tons in fiscal year 1971. The Alwaye plant, Kerala State, processed 4,165 tons of monazite during the fiscal year and produced 4,920 tons of rare-earth chloride, 55 tons of rare-earth fluoride, and 37 tons of rare-earth oxide.

Sales of rare-earth chloride increased to 4,820 tons valued at $1,128,000. Sales of

[e] Estimate. [p] Preliminary. [r] Revised. W Withheld to avoid disclosing individual company confidential data.

[1] In addition to the countries listed, Indonesia and North Korea produce monazite, but information is inadequate to make reliable estimates of output levels.

[2] Year beginning April 1 of that stated.

[3] Exports.

rare-earth fluoride and rare-earth oxide, however, declined to 40 tons and 25 tons, respectively.

IRE announced plans to assess the monazite content of mineral sand deposits along the Orissa coast with the possibility of constructing a mineral separation plant in Orissa similar to that at Chavara and Manavalakurichi.[13]

Indonesia.—State-owned Perussahaan Negara Tambang Timah, (P. N. Timah) planned to extract monazite and xenotime as a byproduct of tin mining. Expansion of facilities to increase tin production and separate rare-earth minerals as marketable concentrates was reported.[14]

Japan.—Brazil reportedly suspended exports of rare-earth chlorides to Japan late in the year, forcing processors to seek other sources of supply and causing at least one company, Santoku Metal Industrial Co., to modify production methods. Imports from European sources increased and Wako Bussan Co. signed a contract for the import of 1,800 tons of rare-earth chlorides from India during 1973 at $0.26 per pound, f.o.b., a 15% increase over the price paid for imports in 1972.[15] Imports of raw material from Australia are planned for 1975.

Production of cerium oxide increased from 126 tons in 1971 to an estimated 181 tons in 1972. Lanthanum oxide production likewise increased from 105 tons in 1971 to an estimated 111 tons in 1972. Shipments of cerium oxide and lanthanum oxide were about 187 tons and 118 tons, respectively.

Total consumption of rare-earth products in 1972 increased by 15% over that of 1971 to 1,384 tons. Consumption of mischmetal increased by 27% to 308 tons (165 tons for steel, 143 tons for pyrophoric alloys), yttrium oxide and europium oxide increased 24% to 23.5 tons, and cerium oxide increased 23% to 171 tons. Lanthanum oxide, however, declined 14% to 171 tons. Consumption in 1973 is projected to increase 10.5% to 1,528 tons.[16]

Development and production of rare-earth magnets continued to receive considerable attention. Tohoku Metal Industries, a producer of samarium-cobalt magnets, developed and began marketing a cheaper mischmetal magnet during the year.[17]

Shin–etsu Chemical Industry Co. Ltd., with technology supplied by Masushita Electric Industrial Co., planned production of cerium-cobalt magnets early in 1973.[18]

Sri Lanka.—The Ceylon Mineral Sands Corp. announced plans to construct an integrated mineral sand facility at Pulmoddai. The China Bay facility for the extraction of rutile and zircon would be dismantled and reconstructed at the site of the present Pulmoddai facility.[19] Upon completion, the complex will have an annual capacity of 200,000 tons of raw sand yielding 500 tons of monazite, among other heavy minerals.

South Africa, Republic of.—The Industrial Development Corp., of South Africa Ltd. (IDC) and KRC Resources S.A. Pty. Ltd., a subsidiary of King Resources, announced a joint venture to investigate a beach sand desposit containing rare-earth minerals discovered in the Richards Bay area of Natal.[20] Plans include the construction of a $455,000 pilot plant to determine the economic feasibility of the project.

Rare Earth Investments (Pty.) Ltd. was formed after the discovery of a rare-earths deposit in the Pilanesburg alkaline complex, 35 miles north of Rustenburg.[21] The deposit is estimated to contain 30 million tons of ore to a depth of 328 feet. Analyses of exposed ore veins indicate REO contents from 7.5% to 39%. Rare-earth processors in France, West Germany, and Japan are reportedly interested in the deposit.

U.S.S.R.—Kolon Trading Co., Inc., U.S. sales agent for rare-earth metals exported by Techsnabexport, Moscow, concluded an agreement for the import and sale in the United States of selected metals, including rare-earth metals, produced in the Soviet Union.[22] Total value of metals to be imported is estimated at $10 million.

TECHNOLOGY

Efforts to effectively utilize the catalytic properties of rare-earth compounds received considerable attention during the year. Rare-earth oxides were demonstrated, under controlled laboratory conditions, to be effective in the oxidation of carbon monoxide in auto exhaust emission controls with lifetimes comparable to platinum, the currently favored catalyst for use in this application.[23]

The Bureau of Mines tested rare-earth oxides for catalytic activity in ethanide dehydration, nitric oxide decomposition, and the hydrogen-oxygen reaction which occurs in hydrogen-powered fuel cells. Catalytic activity varied among the six oxides tested with praseodymium showing the most favorable results.

The potentially large market for samarium-cobalt alloys has led to increased efforts to develop more efficient recovery for samarium and improved processing techniques for permanent magnet fabrication. A solvent-extraction system for recovering Sm_2O_3 from a light-group rare-earth mixture was discussed.[24] Production of samarium-cobalt magnets using a single phase sintering aid, reportedly for the first time, was announced.[25]

Results of a small pilot plant designed to test a solvent extraction technique for the coextraction of uranium and thorium thereby leaving a clear solution for possible rare-earths recovery were discussed.[26]

Bureau of Mines efforts to reduce the costs of rare-earth metals and expand applications centered around yttrium and yttrium master alloys. Electrorefining of yttrium metal from low melting yttrium-base alloys in molten halide salts was studied.[27] Yttrium alloys containing nickel, iron, and manganese were found to be suitable anode feed, whereas yttrium-copper and yttrium-magnesium alloys were not suitable starting materials. Yttrium-magnesium alloys containing up to 55 wt-% yttrium were prepared in an electrowinning cell.[28] Alloys of this type are useful as additives to other materials having rare-earth metals as minor constituents and as intermediates in the production of pure rare-earth metals. Studies of electrolytic methods for preparing yttrium-aluminum and yttrium-iron master alloys using oxide feed materials continued. The addition of small amounts of yttrium to such superalloys as Fe-Cr-Al is estimated to increase oxidation resistance by a factor of 15 to 2,100°F. Such alloys have numerous high temperature applications, including thermal reactors for automotive pollution control. A discussion of the preparation, properties, and present and potential availability of one such alloy was provided.[29] Several automotive thermal reactors using the alloy have been fabricated and made available to an automotive manufacturer for performance evaluation.

The announcement that the first X-ray laser had been developed[30] enhancing the possibility of an X-ray microscope for analyzing nuclear structures aroused considerable interest and controversy.[31] X-rays were reportedly produced when a neodymium-doped laser was focused on a sandwich of aqueous copper sulfate solution between two glass microscope covers.

Lower costs, improved quality, and increased application of rare-earth crystals may be possible as a result of a new production technique developed during the year. Gadolinium-gallium-garnet was produced by a computer controlled growing method which does not require manual control or observation.[32] In another development involving crystal growth technology yttrium-aluminum-garnet was grown using light from a high-pressure xenon lamp as a heat source.[33]

[32] American Metal Market. Crystals of Gadolinium Produced at Bell Labs. V. 79, No. 176, Sept. 26, 1972, p. 11.

The expanding market for rare-earth metals as iron and steel additives continued to attract attention. The use of high-strength, low-alloy steel for specialized applications, such as arctic pipelines, requiring considerable transverse strength to withstand internal pressure and cold represents a substantial market for rare-earth metals. The mechanical properties of a steel composition recommended by Molycorp, containing mischmetal to control sulfide shape for desulfurization, were evaluated.[34] Yield strength, transition temperature, and ductile fracture energy values were found to meet arctic gas pipeline requirements.

The effect of mischmetal additives on commercially produced Ni-Cr-Mo steel was studied.[35] Transverse toughness was improved but the rare-earth additive had no effect on temper embrittlement, although the increased toughness offset much of the embrittlement tendency. In a discussion of die casting alloys, mischmetal was reportedly more effective than silicon in improving creep resistance as the aluminum content of magnesium die casting alloys decreased.[36]

The growing concern over an impending energy shortage and pollution of the environment by conventional fuels has increased interest in other forms of energy, including hydrogen. Hydrogen can be stored as a gas under pressure or in liquid form although such storage presents large-scale distribution, safety, and end-use problems. Evaluation of a storage system using hydrides based upon rare-earth-transition metal compounds, among other materials, to absorb hydrogen for subsequent release by lowering the pressure or raising the temperature, is planned.[37]

Magnetic bubbles were observed for the first time in amorphous films made of gadolinium-cobalt and gadolinium-iron. Such films, used for computer circuits, can be deposited on such materials as flexible plastics and are reportedly cheaper and easier to make than the crystalline variety.[38]

Rhenium

By Larry J. Alverson [1]

Domestic rhenium production decreased but was adequate to meet the more greatly reduced demand for bimetallic platinum-rhenium catalysts, rhenium's major end use. As a result of decreased demand, there was a decline in the price of both metal powder and compounds, and an increase in stocks. Substitution of other metals for rhenium in bimetallic catalysts was primarily responsible for the decreased demand. The rhenium supply was augmented during the year by the importation of a significant amount of ammonium perrhenate (NH_4ReO_4), primarily from Sweden, the United Kingdom, and West Germany.

DOMESTIC PRODUCTION

Production of rhenium, a secondary by-product material recovered primarily from molybdenite (MoS_2) associated with southwestern U.S. and Chilean porphyry copper ores, decreased in 1972 to an estimated 6,100 pounds of rhenium contained in rhenium salts. Cleveland Refractory Metals (CRM), a subsidiary of Kennecott Copper Corp., remained the leading rhenium producer in the United States. The company processed domestic molybdenite concentrates from operations of Kennecott and Magma Copper Co., a subsidiary of Newmont Mining Corp., as well as concentrates from Chilean sources, at its Garfield, Utah, roasting facility.

During 1972, Continental Rhenium Corp., a wholly owned subsidiary of Continental Ore Corp., became the nation's fifth rhenium producer, processing MoS_2 concentrate from Arizona, Canada (British Columbia), Chile, and Peru, at the corporation's Golden, Colo., plant. Preliminary information indicates recoveries in excess of 95% have been achieved due to the application of a new patented process (see technology section) for recovering rhenium.

Production of rhenium bearing molybdenite from porphyry copper ore continued at Magma's San Manuel mine in Pinal County, Ariz. M&R Refractory Metals, Inc., at its Winslow, N.J., plant, produced rhenium salts from the MoS_2 of Magma's San Manuel copper operations for Engelhard Minerals & Chemicals Corp. on a contract-conversion basis. Shattuck Chemical Co., Denver, Colo., a division of Engelhard Minerals & Chemicals Corp., recovered rhenium salts from Arizona molybdenite concentrates. Molybdenum Corp. of America (Molycorp) recovered rhenium salts from MoS_2 concentrate associated with porphyry copper ores in Arizona and primary molybdenite from the Questa molybdenum mine in New Mexico. Molycorp de-

[1] Industry economist, Division of Ferrous Metals.

veloped a new hydrometallurgical process to produce molybdenum and rhenium compounds. This process, developed in cooperation with the Colorado School of Mines Research Institute, prevents sulfur dioxide (SO_2) pollution of the atmosphere, which occurs in conventional roasting of molybdenite. The new process is reportedly unique in its ability to produce high purity products at high yield from substandard MoS_2 source material and has been successfully tested in a small production unit for several months. Molycorp applied for patents throughout the world and was holding licensing discussions with interested companies in the United States and Europe at yearend. The rhenium facilities at Washington, Pa., operating at minimal rates during the first half of 1972, were put on standby and remained that way for the remainder of the year owing to prevailing market conditions.

Newmont Exploration Ltd., a subsidiary of Newmont Mining Corp., installed a multihearth furnace for controlled atmosphere roasting tests at its Danbury, Conn., metallurgy research center as part of its research into a new method of molybdenum-rhenium separation. Much of the work will involve studies of molybdenite concentrate roasting. The molybdenite from the San Manuel mine of Newmont's wholly owned Magma Copper Co. has a high rhenium content, and a new roasting process could yield greater returns than currently obtained by selling concentrate to others for treatment.[2]

Other domestic molybdenite roasting facilities that might be adapted for rhenium recovery include those of Climax Molybdenum Co. at Langeloth, Pa., Duval Corp. at Mineral Park, Ariz., Duval-Sierrita Corp. at Esperanza, Ariz., and Republic Steel Corp. at Canton, Ohio.

CONSUMPTION AND USES

Approximately 85% of estimated 1972 rhenium metal consumption of 4,300 pounds was used in alumina-based bimetallic platinum-rhenium catalysts for refining unleaded, high-octane gasoline. Atmospheric pollution considerations during the last few years have given this application added impetus; however, in 1972, consumption decreased considerably, owing primarily to the substitution of other metals (probably mostly iridium) for rhenium in bimetallic catalysts.

Engelhard Minerals & Chemicals Corp. developed a new series (E-600) of platinum-rhenium catalysts that initially prove to have better stability, better yield as activity declines, and an unlimited number of regenerations and reactivations without significantly impairing catalyst performance. Algeria and the Soviet Union contracted to use the new catalyst in major new complexes in their respective countries.[3] The E-600 series catalysts supplements the older E-500 series catalysts, which are extensively used in the free world's reformers.

Mowhawk Petroleum Corp. completed 3 years of operation using Universal Oil Product's (UOP) bimetallic platinum-rhenium catalyst, type R–16, without a single regeneration or shutdown for catalyst screening. The catalyst service at the end of this first cycle was equivalent to 300 barrels of naphtha per pound of catalyst. The charge rate during the 3 years of operation was essentially constant at 2,600 barrels of naphtha per stream-day.[4]

Two refiners, one Japanese and one domestic, have agreed to use Chevron's new type "D" catalyst for the manufacture of high-octane gasoline-blend stocks in new Rheniforming installations. Presently 29 refineries in the United States, Canada, Europe, and Japan are using type "A" and "B" Rheniforming catalysts.[5]

There are seven low-pressure (200 pound per square inch gauge) Rheniformers currently in service with a total capacity of 120,000 barrels per day.[6] Presently, approximately one quarter of all petroleum reforming catalysts are of the bimetallic platinum-rhenium variety.

The straight platinum (monometallic) catalysts are rapidly being replaced by bimetallic catalysts such as platinum-rhenium. However, research is continuing to find substitutes for the rhenium part of the catalyst. Gold, gallium, germanium, indium, and iridium are being tested and evaluated as replacements for rhenium. Iridium seems to have gained a foothold in the market, notably with the introduction by Exxon Research of its new KX-130 "multimetallic" reforming catalyst containing platinum, iridium, and possibly a third element.[7]

[5] The Oil and Gas Journal. Chevron Develops New Catalyst. V. 70, No. 47, Nov. 20, 1972, p. 48.

[6] The Oil and Gas Journal. Cat-Reforming Pressure Drops Again. V. 70, No. 20, May 15, 1972, pp. 124–136.

The remaining 15% of estimated domestic rhenium consumption was in X-ray tubes, refractory-metal alloys, high-temperature thermocouples, temperature controls, electronic devices, vacuum tube and flashbulb filaments, coatings, electrical contacts, and research and development.

Tungsten-rhenium thermocouples are experiencing increased usage for high temperature measurement, other than that in a nuclear environment, which use has been recently found to be better served by tungsten-molybdenum thermocouples, which exhibit less deterioration. It appears that tungsten-rhenium thermocouples may find additional application in measuring and controlling combustion chamber exhaust temperatures of turbine engines.

During the 1969–71 period, there was a decline in the use of fabricated devices of rhenium owing to curtailment of aerospace programs; however, rhenium is currently finding increased usage in the fabrication of devices for use in X-ray tubes.

A Bureau of Mines Information Circular was published in early 1973 that contains information on rhenium from geologic background and analysis to supply-demand patterns and trends.[8]

PRICES

Prices paid for rhenium metal powder used in rhenium metal wire and mill products during the year ranged from about $975 to $1,400 per pound, depending on quantity, decreasing toward the former by yearend. Prices paid for perrhenic acid used in catalytic applications ranged from about $875 to $1,350 per pound, trending toward the former in the second half of the year.

During the year, the country's leading rhenium producer, quoted rhenium metal powder and perrhenic acid prices closely within these ranges. In August, Shattuck Chemical Co. cut its price on rhenium metal powder to $975 per pound, and that on perrhenic acid to $875 per pound. The company claimed that its price reductions were made possible by its recent plant expansion.

FOREIGN TRADE

Imports of unwrought rhenium metal during 1972 decreased 55% from that of 1971, and totaled 168 pounds valued at $125,751. These imports, all of which represented rhenium metal powder, came from West Germany (85%), and France (15%). There were no imports of scrap or wrought rhenium metal during the year. Unwrought rhenium imports are believed to have been recovered from byproduct molybdenite obtained from porphyry copper ore mined in Chile. The average price of unwrought rhenium metal imports, excluding U.S. duty, was $749 per pound, and ranged from $713 per pound (West Germany), to $952 per pound (France).

A significant amount of rhenium in the form of ammonium perrhenate (NH_4ReO_4) salts was imported primarily from Sweden, the United Kingdom, and West Germany. This material imported under the basket classification "Ammonium Compounds, not specifically provided for" (TSUS 417.44), totaled approximately 1,183 pounds of contained rhenium, valued at $1,357,078.

The import duty on rhenium metal from non-Communist countries remained at the January 1, 1972, rate of 5% ad valorem for unwrought rhenium metal and scrap, and 9% ad valorem for wrought rhenium metal. The import duty on wrought and unwrought rhenium metal from Communist Bloc countries also remained unchanged at 45% ad valorem and 25% ad valorem, respectively. The duty on imports of ammonium perrhenate from Communist and non-Communist countries was 25% ad valorem and 4% ad valorem, respectively.

WORLD REVIEW

Canada.—The Island Copper mine of Utah International Inc., (UI) on Rupert Inlet near Port Hardy, British Columbia, which contains some of the richest known rhenium concentrations in the world, continued to market rhenium and molybdenum concentrates. Two hundred and fifty tons of molybdenum concentrate was sold in 1972, about 14% of designed capacity. In some cases the molybdenum buyer purchased the contained rhenium, while in others, the rhenium was returned on a "toll" basis in order for UI to seek prospective buyers.[9] The estimated rhenium content of the ore body based on copper ore reserves of 280 million tons with 0.53% copper and about 0.027% MoS_2, is over 270,000 pounds, assuming 90% recovery of rhenium from molybdenite.

The Lornex mine of Rio Algom Mines, Ltd., a subsidiary of the Rio Tinto-Zinc Corp., situated in the Highland Valley area of British Columbia, is Canada's newest and largest open pit copper-molybdenum producer. Estimates of the ore body indicate reserves of 293 million tons of ore averaging 0.43% copper and 0.014% MoS_2.[10] Rhenium is present in the ore body but its content has not been established. However, using the rhenium content of nearby operations as a rough base, an estimated rhenium content of about 75,000 pounds can be inferred.

Chile.—A new rhenium plant at Concepción was scheduled to come onstream in 1974–75. A Western European firm together with Cía. de Acero del Pacífico S.A., (CAP) financed a successful pilot plant at the Hazen Research Center in the United States. The industrial plant will be designed to deliver high-grade molybdenum chemicals with the byproduct rhenium as either a chemical-grade rhenium salt or perrhenic acid ($HReO_4$). The production target calls for a yearly rhenium output of 3,300 pounds.[11]

[9] Utah International Inc. Annual Report 1972. 32 pp.
Mining Engineering. Island Copper Starts Up. V. 24, No. 7, July 1972, p. 8.

[10] Mining Magazine. Lornex. V. 128, No. 3, March 1973, pp. 154–163.

The privately owned Chilean firm Carburo y Metalurgia S.A. (Carbomet) has been producing a technical-grade ammonium perrhenate (NH_4ReO_4) since December 1970. The firm is currently enlarging its plant facilities in Nos, Santiago, to increase rhenium capacity in 1973 from 2,000 to 2,700 pounds per year of rhenium contained in technical-grade ammonium perrhenate salt.[12]

Chilean molybdenum and rhenium resources show about 7,700 pounds per year of rhenium as a recoverable figure from the three big State-owned porphyry copper mines. There are additional potentially important rhenium resources from new Chilean porphyry copper deposits, such as Mocha, Cerro Colorado, El Abra, Andacollo, Loica, Pelambres, and others.

The Corporación del Cobre (CODELCO) announced commencement of feasibility studies on a plant to extract molybdenum, rhenium, and other rare metals from porphyry copper ore of the recently nationalized (1971) Rio Blanco copper deposit. The deposit was previously worked by the Cerro Corp. of the United States. According to CODELCO, the plans envisage a $2.6 million plant to be established in the Rio Blanco region about 90 miles northeast of Santiago. The plant is expected to become operational by mid-1973.[13]

Japan.—Shiba, Japan, is the site of Engelhard's newly commissioned magnaformer installation, utilizing the greatly improved E–601 platinum-rhenium bimetallic catalyst for the manufacture of unleaded, high-octane gasoline.[14]

Taiyo Mining and Industrial Co., Ltd., was granted an exclusive license for use of a new hydrometallurgical process developed by Molycorp to produce molybdenum oxide and rhenium compounds.

Mongolia.—The giant copper-molybdenum deposit at Erdenetiyn-ovoo was first investigated by a joint Mongol-Czechoslovak geologic expedition in 1964–65. In 1970, rhenium and other metals were identified in the deposit; however, the rhenium content has not yet been assayed. A new agreement with the Soviet Union for the exploitation of the deposit seems imminent.[15]

TECHNOLOGY

The Bureau of Mines electrooxidation technique was successfully applied to the recovery of molybdenum and rhenium from sulfide ores and concentrates at its Reno Metallurgy Research Center. Extraction of 99% of the molybdenum and rhenium was found to be feasible on a bench scale with an immersion-type electrode system. Similar results were obtained in larger experiments using a 1,260-ampere, bipolar, flow-through cell, except that the power requirements per pound of molybdenum were substantially reduced. This process eliminates the use of the conventional roasting techniques, which are the main factors contributing to sulfur dioxide pollution of the atmosphere.

Concomitant studies on the extraction and separation of molybdenum and rhenium from process solutions have resulted in development of an amine extraction-carbon adsorption system that is capable of recovering 99% of the rhenium as 99.99%-pure ammonium perrhenate, and 99% of the molybdenum as high-purity ammonium molybdate.

The Bureau also investigated hydrometallurgical processing of low-grade molybdenite rougher flotation concentrates as a means for improving byproduct molybdenum and rhenium recovery from porphyry copper ores. Several methods were investigated, and the best rhenium and molybdenum recoveries from the leach liquor were obtained by adsorption of the rhenium from the basic liquor with an anion exchange resin, acidification of the residual liquor, followed by recovery of the molybdenum by adsorption with activated charcoal. The rhenium was recovered from the loaded resin by stripping with ammonium thiocyanate.

Kennecott Copper Corp. received a patent for a process that simultaneously reduces atmospheric pollution and recovers rhenium values in the gaseous effluent from copper smelting operations. The process involves scrubbing volatilized rhenium oxide and sulfur oxide with an aqueous alkaline solution to remove most of the sulfur oxide from the gas stream as a soluble sulfite and to dissolve the rhenium oxide in the resulting sulfite solution. The rhenium-bearing sulfite solution is treated by known means, such as ion exchange or solvent extraction, to recover the contained rhenium oxide.[16]

[15] Far Eastern Economic Review. Precious Cairn. V. 80, No. 14, Apr. 9, 1973, p. 24.

A patent was issued to Continental Ore Corp. for recovery of rhenium and molybdenum values from solution. The process involves extracting soluble molybdenum and rhenium values with an amine solvent, and stripping the values from the amine extract with an ammonium hydroxide solution. The rhenium is then concentrated and recovered from the crystallization mother liquor by amine solvent extraction. It is stripped from the resin using a sodium hydroxide solution and extracted into a pyridine solvent, which is distilled away leaving the desired rhenium salt.[17]

Early in the year, a patent was granted for a process that regenerates deactivated platinum-rhenium reforming catalysts to the condition of fresh reforming catalysts.[18] Dependent on its cost and applicability, this or similar processes should attract the interest of many catalyst manufacturers and petroleum-refining companies.

Chevron Research Co., a subsidiary of Standard Oil of California, developed a new catalyst known as Rheniforming type "D" to help refineries meet no-lead and low-lead motor fuel requirements. The new catalysts reportedly will cost less, provide better yields, have greater stability, and require smaller amounts of platinum.[19]

Kennecott Copper Corp. was granted a patent on a new process for extracting molybdenum and rhenium from raw materials. In the process, molybdenum and rhenium values are recovered from molybdenite concentrate by roasting in the presence of calcium compounds to produce water-insoluble calcium molybdate and water-soluble calcium perrhenate. The need for extensive gas-cleaning equipment to prevent SO_2 discharge is eliminated by the process. The calcine is leached with water to separate rhenium from the molybdenum values, and then leached with acid to solubilize the molybdenum. Alternatively, the calcine is leached with acid, and the dissolved rhenium and molybdenum values may be recovered separately from the clarified solution by use of extraction and stripping cells and/or ion-exchange resins.[20]

A process was patented for the removal of rhenium and other metallic impurities from a sulfide-bearing molybdenite ore. The process, which does not evolve sulfur dioxide, thus eliminating a potential air pollution problem, comprises (1) roasting ore with alkali metal carbonate, (2) leaching 95% of the molybdenum from the resulting fusion mass, (3) oxidizing the leached mass, and (4) treating it with water to extract the rhenium and molybdenum from other metallic impurities before recovering the rhenium and molybdenum by conventional procedures.[21]

Engelhard Minerals & Chemical Corp. studied tungsten-rhenium thermocouple junctions to determine how and under what circumstances tungsten-rhenium wire could be joined and still maintain adequate handleability. It was found that a reliable, sound, and handleable thermocouple junction can be obtained by tightly twisting tungsten-rhenium wire and welding the ends. To be effective, there must be at least one and one half turns of wire prior to the weld. Repeated tests with over 75 junctions fabricated by this technique have resulted in no failures traceable to a properly executed twist.[22]

A study was carried out in the Ledgemont Laboratory of Kennecott Copper Corp. on the oxidative vaporization of rhenium from natural molybdenite concentrates under controlled conditions. The molybdenite oxidation and rhenium vaporization were measured, respectively, by the amount of SO_2–SO_3 and by the amount of rhenium collected in an aqueous absorber as a function of time. The rate of rhenium vaporization increased with the oxygen content of the reactant gas. Consistent with the molybdenite oxidation, rhenium volatilization increased markedly with temperature. The experiments confirmed the general relationship between rhenium vaporization and molybdenite oxidation. With the volatility of rhenium shown under ideal conditions, it is suggested that in multiple hearth roasters, there is oxidation and vaporization in the lower hearths followed by reduction and recondensation of rhenium in the upper stages.[23]

Salt

By Robert T. MacMillan[1]

Production of salt in 1972 declined slightly for the second consecutive year following a 12-year period of steady growth. The quantity actually sold or used by producers, however, increased 2% compared with the 1971 figures. This increase was attributed to a large inventory of unused rock salt carried over from the previous year. The average value of salt sold or used in 1972 declined 4% compared with the 1971 value.

Exports increased 30% in quantity and 33% in value compared with corresponding 1971 figures. Imports, however, declined 10% in quantity and 17% in value.

Legislation and Government Programs.—Tightened antipollution standards set by Federal and State environmental pollution control agencies resulted in the final closing of Olin Corp.'s chlorine-caustic soda plant, Virginia's lone salt producing company. The cost of modernizing the plant to meet more stringent effluent standards was considered too high, and production was phased out early in 1972.

DOMESTIC PRODUCTION

Seventeen States recorded salt production in 1972. The two leading States, Louisiana and Texas, produced 52% of the total output. Ohio, New York, and Michigan contributed 36%. Salt was produced by 54 companies at 96 plants in the United States and Puerto Rico in 1972. Eleven companies, each producing more than 1 million tons in 1972, operated 42 plants and accounted for 85% of the total salt output. Eighteen companies with a production of less than 1 million tons but more than 100,000 tons operated 28 plants and accounted for 14% of the total production. Twenty-five other companies whose individual production was less than 100,000 tons operated 26 plants and supplied the remaining 1% of the total salt output.

Fifteen plants, each with a production of over 1 million tons, accounted for 64% of the total salt output. Ten plants, each producing between 500,000 and 1 million tons, accounted for 14% of the total. The remaining 22% was supplied by 71 plants.

A trend toward consolidation in the salt industry continued with Solar Salt Co. of Utah being sold to American Salt Corp. Dakota Salt Co. of North Dakota was ac-

quired 2%, totaling 60% for the chemical industry as a whole in 1972. This compared with 61% for the previous year.

The second largest use of salt was for deicing streets and highways and for roadbed stabilization. This use, which is tabulated in table 7 opposite "Highway use," formerly "States, counties, and other political subdivisions (except Federal)," required 20% of the salt output in 1972 compared with 18% in the previous year. Salt used for food and food-related uses was 6.5% of the total consumed compared with 6.4% in 1971. The categories included in food-related consumption were as follows: Meat packers, tanners, etc.; fishing, dairy, canning, and baking; flour processing; other food processing; and grocery stores. Salt sold to grocery stores was assumed to be largely for table use; however, some salt in this category may have been used for water softeners.

PRICES

Prices per 100 pounds of salt quoted in Chemical Marketing Reporter for various grades in 1972 were as follows:

	January	June	July	December
Salt, evaporated, common, in bags, carlots, or truck lots, works	$1.43	$1.43	$1.43	$1.43
Salt, chemical-grade, same basis	1.54	1.54	1.54	1.54
Salt, rock, medium, coarse, same basis	.97	.97	.97	.97
Salt, rock, extra coarse, same basis	1.02	1.02	1.02	1.02

The average value of evaporated salt reported by producers to the Bureau of Mines in 1972 was $21.26 per ton. On the same basis the average value of rock salt was $6.31, and that of salt in brine was $3.29.

FOREIGN TRADE

Exports of salt increased 30% in 1972, compared with the 1971 figure, but were less than 2% of the total production. Canada and Japan were the chief recipients. Exports to Canada increased 58%, and exports to Japan decreased 15%.

Imports of salt decreased 10% in volume and 17% in value in 1972 compared with corresponding figures in 1971. Mexico became the chief supplier with 36% of the total; Canada, formerly our chief supplier, was second with 29%; and Bahamas with 25% was third. The remaining 10% came from several countries. Imports were 7.3% of the apparent consumption for the United States in 1972.

WORLD REVIEW

Australia.—Dampier Salt Ltd. made its first shipment of salt to Japan from a 2-million-ton-per-year solar-salt-producing facility in western Australia. The newly expanded facility jointly owned by Japanese and Australian interests initiated production in 1971. A condition of oversupply on the international salt market was blamed for the temporary halting of shipments from Lefroy Salt Co., a smaller Australian firm.[2]

Brazil.—Essentially all Brazilian salt was produced by solar evaporation of seawater in the States of Rio Grande do Norte and Rio de Janeiro. A large salt terminal was expected to be completed at Areia Bronca in Rio Grande do Norte in 1972. The terminal built on an artificial island was designed to accommodate ships ranging up to 100,000 tons. The salt was to be barged from and to the mainland.[3]

India.—Seawater continued to be the chief source of salt in India. It was recovered from coastal areas of Gujarat, Maharashtra, Kerala, Tamil Nadu, Andhra Pradesh, Orissa, and West Bengal. Salt was also produced from inland lake and subterranean brines at Sambhar Lake, Didwana, Phalodi Pachpadra, and Kuchaman.

[e] Estimate. [p] Preliminary. [r] Revised. NA Not available.

[1] Salt is produced in many other countries, including Cape Verde Islands and Libya, Mauritania, and Niger, but quantities are relatively insignificant or reliable data are not available.

[2] 1970 and 1971 data are sales.

[3] Includes an average annual production in the Canary Islands of 15,000 tons of marine salt.

[4] Includes small quantities of sodium sulfate and sodium salts other than sodium chloride.

[5] Year beginning March 21, of year stated.

[6] Marine salt only.

[7] Less than ½ unit.

Rock salt was produced at Guma, Maudi District, Hunachal Pradesh. Reserves of rock salt in the Maudi District were estimated at 7.6 million tons.[4]

Italy.—The Trapani Salt Flats, the site of a solar salt industry for more than 2,000 years, will be closed according to an announcement by the Sicilian Government. Outdated, hand-labor production methods unchanged from the Middle Ages were cited as an important factor in the closing. The fact that the land was more valuable as construction sites for tourists' cottages was also considered.[5]

Netherlands Antilles.—The first shipment of salt was made from the new solar salt facility of International Salt Co. at Bonaire on the Island of Aruba. The new salt facility was reported to have a potential production capacity of 400,000 tons per year.[6]

TECHNOLOGY

The increased use of road salt for "bare pavements" in the snow belt caused concern among ecologists, conservationists, and others involved with problems of environmental pollution. Numerous studies have been made of the environmental effects of the use of road salt in specific localities. One of these studies made in the east-central section of Massachusetts indicated that the continued use of road salt might increase the average steady-state NaCl concentration in ground water by 160 milligrams per liter (parts per million).[7] Drinking water standards ranging from 250 to 500 parts per million have been recommended. Although the concentration of salt that may eventually occur in the ground water in eastern Massachusetts may not be harmful to the general population, persons on special low-sodium diets may be adversely affected. About 22 tons per lane-mile per year were used to salt the roads in the area studied. The Salt Institute, a national association of salt producers, recommended "sensible restraint" in the use of deicing salt.

Production of salt from seawater by electrodialysis rather than by solar evaporation was expected to become a reality in Japan with the installation of a 150,000 ton-per-year plant at Okayama.[8] The operating labor costs of the new plant were one-sixth that for a solar plant, and the 16 electrodialyzers occupied a fraction of the space that would be required by solar evaporating ponds for equivalent salt output. A second plant was expected to open at Nagasaki. The Nagasaki plant was to produce chlorine, caustic soda, and hydrogen as well as salt.

In the electrodialysis units, semipermeable membranes under the influence of an electrical potential separate the charged ionic particles from seawater producing a brine concentrate from which the salt is crystallized.

Rock salt resources of Oklahoma at depths ranging from 30 to 3,000 feet were estimated at 20 trillion tons in a report by an Oklahoma geologist.[9] Examination of many gas and oil well logs throughout the State provided information on salt deposits which indicated that they were much larger than previously estimated. Three principal Permian salt sequences each 100 to 1,000 feet thick underlie the western half of the State. Individual salt beds are typically 5 to 30 feet thick and are interbedded with reddish-brown shale and possibly anhydrite and gypsum. In addition to the rock salt reserves, five natural salt springs in western Oklahoma produce an estimated total of 6,300 tons of salt per day. The outflow of the springs produce a barren area called a salt plain. The only salt production in Oklahoma is by solar evaporation of brine on these plains. Production costs of salt either as brine or crystallized salt were said to be potentially lower than the average for the nation and could make Oklahoma competitive with the larger salt producing States.

A novel system for recovering geothermal energy was suggested in a patented process in which a "heat well" would be created at great depth in a salt dome or other deep-seated salt formation using available drilling equipment and techniques.[10] Utilizing the high heat conductivity of solid salt formations the heat energy of the earth would be transmitted to the "heat well" where it would be removed and utilized by a suitable fluid circulating through a heat exchanger. The energy collected could be utilized in the mining and purification of salt by recrystallization or for other purposes.

Sand and Gravel

By Walter Pajalich[1]

Sand and gravel production decreased about 1% to 913 million short tons. The value of production increased about 4%. Output from commercial operations was 86% of the total output, while Government-and-contractor production was 14%. The production of sand and gravel in the Nation's leading State, California, increased from 115 million short tons in 1971 to 117 million short tons in 1972.

DOMESTIC PRODUCTION

California, with 117 million tons, ranked first in sand and gravel output and produced about twice as much as second-ranked Michigan. Other States producing substantial quantities of sand and gravel in descending order of production were Ohio, Illinois, Minnesota, Wisconsin, and Texas. Combined production from the seven leading States was 369 million tons, about 40% of the total U.S. output. The value of sand and gravel produced in these seven States was $471 million, 39% of the Nation's total. The number of commercial operations continued to decline from 5,738 in 1971 to 5,384 in 1972.

Factors, which have added to the consumer cost of sand and gravel, included increased labor costs, growing land values, cost of land rehabilitation, longer haulage distances, which increase transportation cost, and the need to produce from lower quality deposits as better ones become depleted or covered by urban expansion.

There were 4,286 commercial operations with production under 200,000 tons per year. These operations accounted for 30% of the total U.S. production. There were 751 operations with production between 200,000 and 500,000 tons, and they accounted for 30% of production. The remaining 347 operations with production over 500,000 tons, accounted for 40% of production.

The use of larger operating units, more efficient portable and semiportable plants, versatility of plant capacity, and greater awareness of pollution control and land rehabilitation were the keynote of progress in 1972.

Anchorage Sand & Gravel Co.'s new plant in Alaska, has a 10-year supply of sand and gravel from several pits in the area. The 400- to 500-ton-per-hour plant has the versatility of making marketable products from a variety of sources. The plant is highly automated with a central console control for the entire operation.[2]

Ohio Gravel Co., Division of Dravo Corp. opened a new 900-ton-per-hour plant at Newton, Ohio. The operation is automated and controlled from a central console. It is monitored by a closed-circuit TV system and coordinated through use of a UHF radio communications system. The stockpile storage area will hold up to 200,000 tons of material. The 75-acre mining property is under lease and is estimated to contain about 5.5 million tons of sand and gravel reserves. The property is on the perimeter of land owned by Dravo Corp. Sand and gravel mined on the property is hauled to the plant on a 2½-mile off-highway road.[3]

Consolidated Rock Co. began working a sand and gravel property at Irwindale, Calif. The deposit is located on the alluvial fan at the mouth of the San Gabrial River. The plant is automated and has a 2,400-ton-per-hour capacity.[4]

[5] Approximate figures for operations by States, counties, municipalities, and other Government agencies under lease.

Victory Sand and Concrete, Inc.'s, new 250-ton-per-hour aggregate plant started operating in June. Sand and gravel is dredged from the Kansas River at Topeka, Kan. Although most of the production will go to the related company May-Ransom-Sheetz, Contractors, Inc., some of the material will be available for commercial sale. The plant has liquid-solids separation equipment, which includes screening units, dewatering screws, and an automatic sand-classifying tank.[5]

A new sand dredging operation near Clermont, Fla., has been started by WSW Mining Co., Inc. The plant has a 550-ton-per-hour capacity. Reserves are estimated at 35 million tons.[6]

The new 385-ton-per-hour sand plant of Brown Brothers Sand Co., Howard, Ga., is supplying sand for concrete, mortar, and special uses as far as 200 miles away. The plant consists of a dredge, scalping screen, washing bins, surge tank, two sand pumps, and four hydrocyclones.[7]

Owens-Illinois sand processing plant in Trampas Canyon east of San Juan Capistrano, Calif., went into production. Products are glass sand, with both amber and flint grades produced.

The You Bet White Co. is mining the high-grade (99.6% SiO_2) Bear River stream gravels below Rollins Reservoir east of Colfax, Calif. The gravel is crushed to minus 350 mesh and sold in the Sacramento area for use as an abrasive in the manufacture of scouring powder. Part of the production is shipped by rail to Oregon for use in silicon carbide manufacture.[8]

About 400 billion tons of commercially significant sand occurs in the upper 10 feet of the ocean floor off the northeastern coast of the United States. These large deposits have immediate useful potential for this part of the country and can also supply some of the eastern Provinces of Canada.[9]

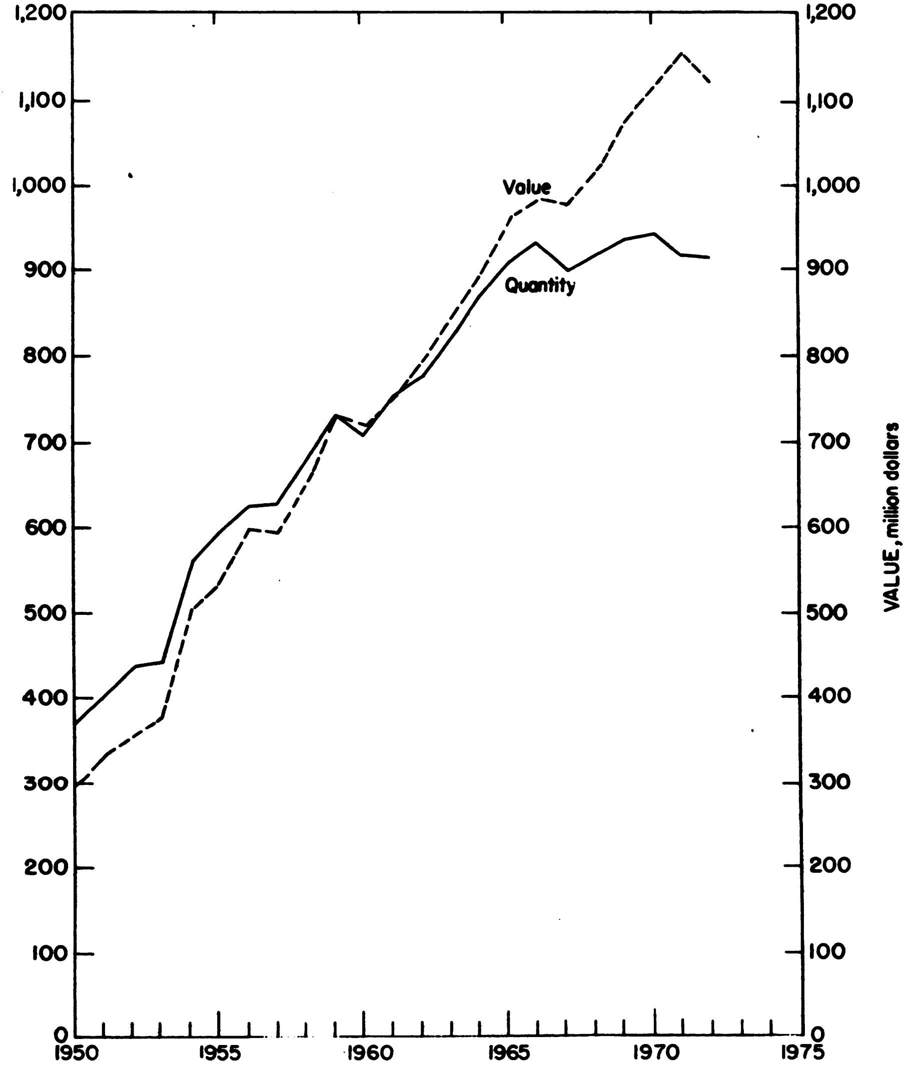

Figure 1.—Production and value of sand and gravel in the United States.

CONSUMPTION AND USES

In 1972, U.S. consumption of sand and gravel amounted to 913 million tons valued at $1.2 billion. The construction industry, the prime user of sand and gravel, consumed 95% of the tonnage. This was 89% of the value of the sand and gravel output in 1972. Of the amount of sand and gravel consumed by the construction industry, 47% went into paving, 39% into building, about 11% into fill, and 3% into other uses. The principal consumers of higher priced industrial sand were the glass and foundry industries.

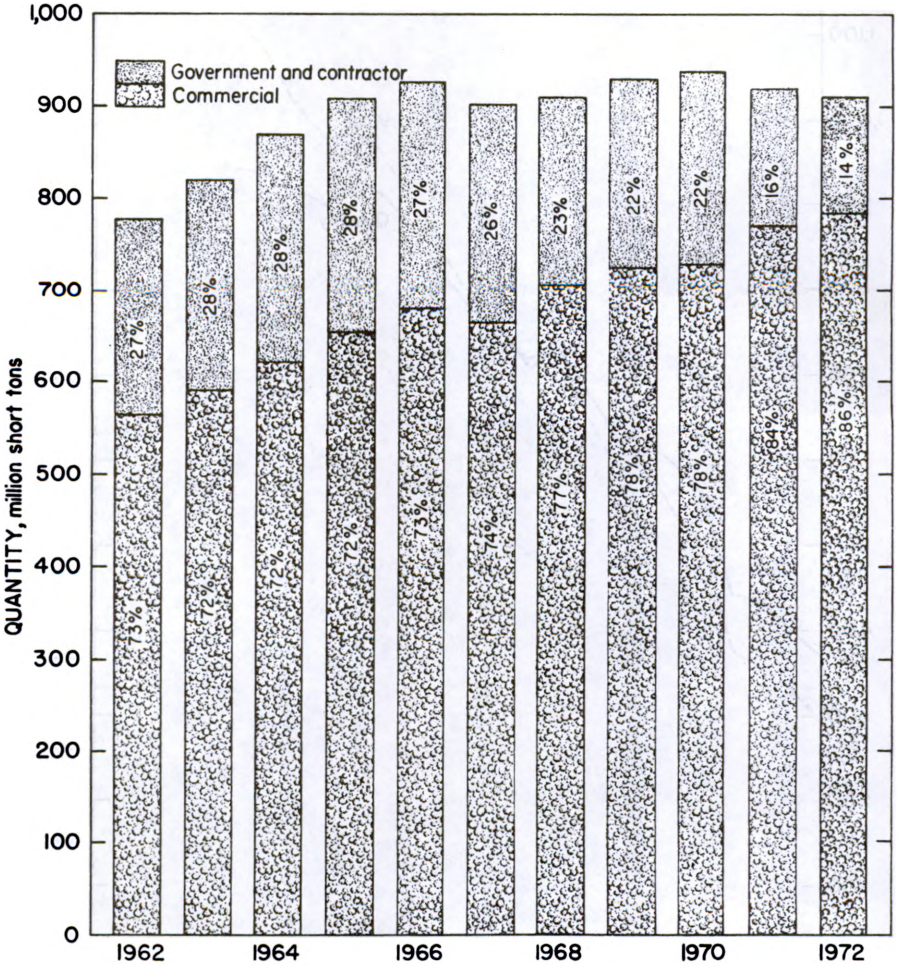

Figure 2.—Sand and gravel sold or used in the United States.

PRICES

Representative carload-lot prices of sand in 19 cities at the end of 1972 ranged from $1.05 per ton in Detroit to $5.40 per ton in Pittsburgh, according to the Engineering News-Record.[10] The average of the sand prices reported was $3.14 per ton, compared with $3.23 per ton in 1971. Prices for either ¾- or 1½-inch gravel ranged from $1.60 per ton in Birmingham to $7 per ton in New Orleans. The average of the ¾-inch gravel prices reported for 20 cities was $3.80 per ton, compared with $3.67 per ton in 1971. For 1½-inch gravel, the average for 18 cities was $3.74 per ton compared with $3.48 per ton in 1971.

The average price of sand in Montreal and Toronto, Canada, at the end of 1972 was $2.30 per ton; ¾-inch gravel was $2.43 per ton, and 1½-inch gravel was $2.35 per ton.

Based on the Bureau of Mines canvass, the average value of sand and gravel sold or used by producers, f.o.b. plant, was $1.31 per ton; the comparable value in 1971 was $1.25 per ton.

FOREIGN TRADE

Canada received 79% of U.S. exports of construction sand, the Bahamas received 20%, and Venezuela received less than 1%. The remainder went to 20 different countries. Exports of construction sand totaled 419,647 short tons, valued at $801,236. Gravel exports totaled 352,560 short tons valued at $462,514. Total exports of common sand and gravel were 772,207 short tons, valued at $1,263,750. Canada received 78% of U.S. exports of common sand and gravel, the Bahamas received 12%, and Mexico received 8%. Of U.S. exports of industrial sand, which amounted to 1,048,775 short tons valued at $5,944,231, Canada received 74%, Mexico 13%, and Colombia about 4%. The remainder went to 59 different countries.

Most of the crude sand and gravel imported in 1971 was from Canada. Almost all of the imported glass sand was from Australia.

WORLD REVIEW

Belgium.—About 90% of Belgian sand and gravel was extracted in the Limburg Province along the River Meuse. The depths of the deposits vary between 30 and 60 feet. Additional sand and gravel was dredged from the River Meuse, where the ratio of gravel to sand was 4:1. In 1972, Belgium produced about 15 million tons of sand and gravel.

Canada.—It has been estimated that aggregate consumption in some Canadian urban centers was about 5.4 tons per person. Consumption is expected to reach 18 tons per person by 1980. Construction activity, particularly heavy or engineering construction, regulates the production of sand and gravel in Canada. The upward trend in production peaked in 1966 to 1967 with the large demand for construction materials related to Expo '67. In the post-Expo years demand decreased and has stabilized to a more normal annual increment of increase. Total sand and gravel production for 1971 was estimated at 201 million tons valued at $134 million. The largest production of 85 million tons was in Ontario province followed by 37 million in Quebec.[11]

A recent survey by the Aggregate Producers Association of Ontario indicated that transportation costs to the consumer represented approximately 60% of the f.o.b. pit selling price of the product. For each mile sand and gravel products are hauled an additional 5 cents per ton was required. The f.o.b. pit selling price ranges from 50 cents to $1.25 per ton. Trucks move 95% of the total production. When the product was moved 5 miles from the source, the transportation cost represented approximately 30% of the total market value, and 40% when the distance was more than 20 miles.[12]

France.—Sand and gravel is found throughout France. Main areas of concentration are in the large valleys of the Seine, Rhone, Loire, and Rhine Rivers. There were about 1,500 producers of sand and gravel in France, many of whom are located in the Seine Valley. The 150 largest producers provide 60% of the national production. The average price f.o.b. plant ranges from $1 to $1.25 per ton of sand and gravel.

Laws that governed the sand and gravel industry dated back to the time of Napoleon I, however in 1970 these laws were changed. Authorization to mine sand and gravel now must include detailed information about the deposit, method of operation, and land restoration.

Although the French Continental Shelf is known to contain large sand and gravel reserves there is little dredging of these deposits. Only 1% of the country's consumption of about 190 million tons of sand and gravel comes from dredging operations.[13]

United Kingdom.—Three new plants have gone into production for Blue Circle Aggregates, Ltd. Located at Elford near Tamworth Staffs, Huntley Wood near Cheadle Staffs, and Repton near Burton on Trent Staffs, these plants will serve the Midland market. They have been designed with up-to-date control, instrumentation, and closed-circuit TV, which enables them to operate with the minimum of personnel. Each plant is capable of producing 10,000 tons of aggregates per week.[14]

The new Parker sand and gravel plant at Chard went into operation after the 40-year-old plant at the site was dismantled. The firm of J. R. Pratt and Son, Ltd., owners of the old and new plants have been in business for over 50 years. The new plant was designed to produce 100 tons per hour.[15]

Near the village of Thurlby Butterley, Blue Circle Aggregates, Ltd., has started dredging a new sand and gravel deposit. A floating pontoon with a 10-inch pump driven by a 370-horsepower diesel engine delivers the material directly to the plant through a floating pipeline. Operating capacity is 120 tons per hour.[16]

In the United Kingdom, production of sand and gravel is usually exceeded only by that of coal. Sand and gravel production in 1972 was about 130 million tons, most of which came from land-based operations. Offshore production began to increase in the 1960's as the demand for materials increased and dredged materials became more competitive. There are at least 15 companies operating between 60 and 70 sand and gravel dredging vessels of varying capacities. About 10% or 13 million tons of sand and gravel was produced by dredging. About one-quarter of the dredged material was exported to the Continent.

Until 1966, production of sand and gravel was greater than crushed stone. In 1972 crushed stone production was about 140 million tons. At present rates of growth, limestone alone is expected to exceed the production of natural sand and gravel by 1974. Much of the future of sand and gravel production will depend on present land restoration methods that will almost certainly govern future release of land for sand and gravel extraction.

TECHNOLOGY

Airborne resistivity mapping known as E-Phase has been developed by Barringer Research, Inc., for mapping sand and gravel deposits. The systems sensing method measures resistivity of the upper 10 to 150 feet of surface. Resistivity airborne surveys allow complete and quick coverage of land that may not be traversed on the ground because of terrain problems or urbanization.[17]

At the Plastic Disposal Research Institute, Funabashi, Japan, a system of converting plastic waste into pavement material was developed. The plastic waste is crushed into small pieces, melted, and the poisonous gas removed. The pieces are then pelletized and passed through a water tank and turned into artificial gravel.[18]

Dramatic upgrading of low-grade sand and gravel has been reported by Young's Sand and Gravel Co., Loudonville, Ohio. Designated as the Rib-O-Matic, the new process uses a horizontal circular plate that supports a bed of material to which crushing and kneading forces are applied by six sets of rubber wheels or rollers. The crushing effect between the wheels and bed of material crushes, then pulverizes, the unsound aggregate while scouring and cleaning the sound aggregate.[19]

Williamstown, Mass., became the first town in New England to pave a road with a mixture of reclaimed rubber and asphalt. The 400-foot section of road was paved with "Ramflex," manufactured by U.S. Rubber Reclaiming Co. About 30 reclaimed tires went into the 1½ inches of asphalt mixture laid down on this stretch of road.

The Pennsylvania Department of Transportation completed 1.8 miles of test paving on high-speed U.S. Route 322 between Harrisburg and Hershey. The material used was a German-originated mastic asphaltic compound, Gussaphalt, which has been successfully used on more than 1,500 miles of prime Autobahn roads in West Germany, and in other European locations, for more than 15 years. The higher cost of this material versus U.S. asphalt pavement reputedly is compensated for by longer life, low maintenance costs, and the ability to carry traffic as soon as it cools. It can be laid in subfreezing temperatures and is highly skid resistant. The compound embodies the use of native lake asphalt, which holds colloidal material in suspension, a property not present in petroleum asphalt. The asphaltic mixture is combined with limestone, sand, and 1-B stone at the originating plant and then transported to the construction site at a maintained temperature of 410 to 450 degrees fahrenheit. A crimper-spiked roller makes a waffle-like pattern in the surface of the finished pavement, which adds to its skid resistance.

New dredge designs have been developed for the hydraulic and bucket-line ladder dredges enabling them to operate in greater water depths than before. Also economical construction of larger dredges is now possible. Some of the new features allow hydraulic ladder dredges to dredge 300 feet or more and bucket-line ladder dredges to dig 200 feet or more below the water level surface. The improved design allows for operation under sea wave and swell conditions, lower ratio dredge displacement weight to capacity, and increased dredge efficiency and production. Design changes include the use of a multiple section articulated ladder, which may comprise two or more ladder sections, and a new principle of compensating for sea and wave swell conditions.

Dust control received considerable attention last year. In most sand and gravel operations, dust suppression is a problem. Suppression can be achieved by confinement of the dust with a curtain of moisture, direct wetting of the dust, or the combining of dust particles with each other by the use of a liquid spray, thus making the dust particles too heavy to become airborne or to remain airborne. Another system of control is the collection of dust or fines. Chemicals are often added to water to increase its' wetting capability.

The Conrock Co. of California has embarked on a full scale dust control program for their production facilities, stockpiles, and roads. The program uses the dust control chemical Coherex in a 1 to 10 part water ratio.[20]

The Hills Materials Co., Rapid City, S. Dak., uses a cyclone dust collector. This resulted in a bag collection of fines that are sold as mineral filler.[21]

The Construction Aggregates Rail Shippers (CARS) Conference study on aggregate shipments by rail, done by A. T. Kearney & Co. Inc., issued its first report. The study found some of the reasons why it is generally unprofitable to move aggregates by rail and made a series of recommendations to aggregate producers and receivers on how they can help the railroads alleviate some of the problems. Most of the recommendations are directed at reducing costs of rail transportation. CARS was organized in 1969 through the sponsorship of the National Crushed Stone Assoc., National Limestone Institute, National Sand and Gravel Assoc., and the National Slag Assoc.[22]

The Soviets have developed a liqiud sand process for ingot mold and steel castings. The mixture can be poured readily into core boxes or molds in which it hardens without any external action such as gassing or drying. Liquid sands are created by adding small amounts of surface acting agents to insure intensive foam-formation as sand and bonding material are mixed together. The mixing changes the plastic state of the material into a state whereby the mixture behaves like a liquid. Self-setting is due to the addition of some solidifying agent that reacts with the bonding material. A variety of sand mixes have been developed. One widely used in steel and iron foundry work is silica sand, with sodium silicate as the bonding material, alkilaril-sulfonates (mostly petroleum sulfoacids) as the surface active mixture, and ferro-chromium production slag containing dicalcium silicate as the setting agent.[23]

Unspecified	268	2,291	362	2,623
Total[3]	1,911	12,893	4,512	21,546

[1] Includes Alabama (1972), Arkansas, California (1972), Connecticut (1971), Florida, Georgia, Idaho (1972), Illinois, Indiana, Iowa (1972), Kansas (1972), Kentucky, Louisiana (1971), Massachusetts (1972), Michigan, Minnesota, Missouri, Nevada, New Jersey, New York, Ohio, Oklahoma, Pennsylvania, South Carolina, Tennessee (1972), Texas, Utah, Virginia, West Virginia, and Wisconsin (1972).

[2] Excludes American Samoa and Puerto Rico.

[3] Data may not add to totals shown because of independent rounding.

Table 11.—U.S. imports for consumption of sand and gravel, by class

(Thousand short tons and thousand dollars)

Year	Glass sand[1]		Sand, n.s.p.f., crude or manufactured, and gravel		Total	
	Quantity	Value	Quantity	Value	Quantity	Value
1970	64	262	815	1,338	879	1,600
1971	48	243	667	984	715	1,227
1972	49	201	712	1,178	761	1,379

[1] Classification reads: Sands containing 95% or more silica and not more than 0.6% oxide of iron and suitable for manufacturing glass.

Silicon

By E. Shekarchi [1]

Major domestic producers of ferrosilicon and metallurgical-grade silicon engaged during 1972 in expansion toward specialization, and/or plant modernization to comply with 1975 antipollution standards set by local governments and the Federal Government.

Domestic production of ferrosilicon and silicon metal in 1972 increased sharply to meet the rising demands of a wide variety of products. However, increased production of ferrosilicon and silicon metal throughout the world led to severe price erosion both domestically and internationally. High-purity and ultra-high-purity silicon metal, though small in volume, continued to be an important element in the electronics industry; shipments were up 18%. The new demand for silicones as sealants for encapsulation of electric parts greatly increased during the year.

DOMESTIC PRODUCTION

On a gross weight basis, net production of ferrosilicon and silicon metal increased 18% in 1972 while shipments were 23% higher than in 1971. Silicon metal for metallurgical uses was produced at 11 plants of seven companies as shown in table 2.

Northwest Alloy, Inc., a newly formed subsidiary of Aluminum Co. of America (Alcoa), planned construction of a magnesium and silicon plant at Addy, Wash. Initial plant capacity will be 24,000 tons per year, and the final annual capacity will reach 40,000 tons. The plant will be the first of its kind in the United States to employ the megatherm (electrothermal) process with dolomite as raw material. This process, in operation at Marignac, France, since 1964, involves the reduction of calcined dolomite by ferrosilicon at a temperature in excess of 1,500° C. The magnesium and silicon metal extracted will be used by Alcoa and will make the company nearly self-sufficient in silicon metal. The Addy plant was scheduled to begin operation in 1975. It is to be the most modern and efficient environmentally controlled facility of its kind. Total cost has been estimated at $50 million.

Table 1.—Production, shipments, and stocks of silvery pig iron, ferrosilicon, and silicon metal in 1972 [1]

(Short tons, gross weight)

Alloy	Silicon content (%)	Producers' stocks as of Dec. 31, 1971 [r]	Production	Shipments	Producers' stocks as of Dec. 31, 1972
Silvery pig iron	5–24	W	W	W	W
Ferrosilicon (includes briquets)	25–55	66,134	491,967	421,200	58,200

Do	Rockwood, Tenn	Do.

Allegheny Ludlum Steel Corp., a major producer of grain-oriented silicon electrical steels, announced a $15 million expansion and improvement program exclusively for the silicon facilities at its Bagdad processing plant in Bagdad, Pa.

Standard Resources Inc. of Nevada expected to be producing market-ready silica flour at a rate of 150 tons per day early in 1973. The material will be marketed as minus 200-mesh or plus 200-mesh silica flour ready for bagging, or for bulk shipment.

CONSUMPTION AND USES

New uses for semiconductors and transistors included transistorized circuitry in electronic stoves, tiny semiconductors in diagnostic computer systems, and large numbers of integrated circuits. U.S. factory shipments of semiconductors in 1972 were

[2] Includes magnesium-ferrosilicon and other silicon alloys.

18% higher than in 1971. Large producers of semiconductors, Texas Instruments, Inc., Motorola Inc., and Fairchild Camera & Instrument Corp., were expanding their production facilities to meet anticipated domestic and foreign demands in 1973.

The range of application of the new silicones, Room Temperature Volcanizers (RTV), increased significantly in 1972. These new products can be poured or spread as a paste which cures to an elastomeric solid at room temperature. The key to this behavior is a chemical reaction which takes place under the catalytic influence of dibutyltin dilaurate, a tin compound. The elastomeric solids were used as sealants in building and engineering, in the production of molds for casting plastics and low-melting-point metals, for coating paper, and for encapsulation of electrical parts.

The consumption patterns of ferrosilicon and silicon metal in the steel and aluminum industries were similar to those of previous years. However, it was predicted by automakers that more silicon alloys would be used in the production of engine castings for economy-size cars in the coming years.

PRICES

The f.o.b. price of 50% ferrosilicon was decreased in March 1972 from 16 to 15 cents per pound contained silicon, bulk, carload lots. The price remained unchanged for the remainder of the year.

Metallurgical-grade silicon, 98% minimum silicon, 0.35% maximum iron, was quoted throughout the year at 25.4 cents per pound. Amorphous silica in 50-pound paper bags, 200 mesh, 90 to 95% silicon, was quoted at $26 per ton, and 98 to 99% silicon was priced at $27 per ton at yearend.

Despite improved steel demand, ferrosilicon prices generally were stable during the year. There appeared to be a tendency in the steel industry to hold raw material inventories down, and buyers were hesitant to make long-term commitments.

FOREIGN TRADE

During 1972 net trade in ferrosilicon, though active, continued to be unfavorable to the United States. Exports decreased 71% in volume and about 61% in value; major recipients were Canada, 3,335 tons; West Germany, 1,617 tons; and the United Kingdom, 1,275 tons. Nineteen countries received shipments ranging in quantity from 1 to 6 tons.

Imports of ferrosilicon and silicon metal for consumption increased 75% in volume and 83% in value over those of 1971. Major increases were in the silicon metal categories. For example, silicon metal imports of not more than 99.7%silicon increased eighteen fold by volume in 1972 compared with 1971 imports. Table 5 has been expanded to include the higher silicon content categories, as reported by the Bureau of the Census.

Table 4.—U.S. exports of ferrosilicon

Year	Quantity (short tons)	Value (thousands)
1970	44,694	$11,887
1971	25,506	5,608
1972	7,367	2,196

WORLD REVIEW

India.—The two major ferrosilicon producers in India were the public sector, Mysore Iron and Steel, Ltd., at Bhadravati and the private sector, Indian Metals and Ferroalloys Ltd., at Bhubaneshwar, Orissa. Output of ferrosilicon and silicon metal during 1972 was approximately 19,000 tons, a slight increase over 1971 production.

The Government Planning Commission estimated that India will consume all of its 1973 ferrosilicon production and that the demand will increase to 31,500 tons by 1975 and to 46,000 by 1980.

Italy.—Construction of a new plant in Sicily which will produce about 148,800 tons per year of silicon metal, ferrosilicon, and ferrochrome continued in 1972. Most of the raw material, except chromite, will come from the plant vicinity.

Japan.—Kanabe Kokoki, which built a completely sealed nonrotating, 45,000-kilovolt-ampere ferrosilicon plant in 1968, completed the construction of two fully sealed rotating electric furnace plants early in 1972. One of these plants, which belongs to Yahagi Iron Company of Nagoya, Japan, reportedly produced 36,000 tons of 50% ferrosilicon in a fully enclosed, pollution-free 60,000-kilovolt-ampere electric furnace without any poking. The other plant, which belongs to Joetsu Ferroalloy Company, has the same specifications and was utilized in the production of 75% ferrosilicon.

Of the estimated 300,000 tons of ferrosilicon produced by Japan in 1972, more than half was of 75% ferrosilicon grade, reflecting a trend toward specialization.

Norway.—The construction of two new electric furnaces for production of silicon metal was completed in 1972. One of the furnaces, belonging to Bremanger Smelteverk, a division of Elkem-Spigerverket, increased the production capacity at its Svelgen plant to 10,000 tons of silicon metal per year. The other furnace, belonging to A/S Meraker Smelteverk, a subsidiary of Union Carbide Corp., has a production capacity of 14,000 tons of silicon metal per year.

Exports of silicon metal from Norway in 1972 totaled 42,000 tons, a 62% increase compared with 1971 exports.

South Africa, Republic of.—A new submerged arc electric furnace, reportedly the largest in South Africa, was commissioned in May 1972 at the Ferrometals Ltd. plant in Witbank. Ferrometals Ltd. is a subsidiary of African Metals Corp., Ltd. (AMCOR), which supplies most of the South African domestic market with metallurgical-grade silicon, ferrosilicon, and other alloys. The furnace has a trans-former capacity of 48 megavolt amperes and was built at a cost of about $4.2 million.

From 1966 to the end of 1971 South African exports of ferrosilicon were reduced drastically in order to meet the needs of the expanding domestic market. However, with the start of new facilities, producers predict an increase of ferrosilicon exports in excess of $7 million per year.

Silver

By J. R. Welch[1]

Domestic mine output of silver was down 10% to 37.2 million ounces. This was 4.3 million ounces less than in 1971, the drop being mainly attributable to an extensive fire at the Sunshine mine in Idaho. Imports exceeded exports in 1972 by 35.7 million ounces, and consumption increased by 17% to 151.1 million ounces (exclusive of coinage). Silver prices fluctuated widely but displayed a rising trend throughout 1972. On January 3 the price was 138.7 cents per ounce, which was the low for the year. A high of 204.8 cents per ounce was reached on December 26, and at yearend the price was 204.2 cents.

While U.S. silver consumption for industrial uses increased significantly, its usage in coinage remained about the same as that in 1971 at 2.3 million ounces. The use of silver for all industrial purposes increased, except for use in bearings. Silver used in commemorative coins and medals rose sharply to an estimated 11.5 million ounces. Trading volume on the New York Commodity Exchange (COMEX) was up 32% over that of 1971. Treasury stocks declined 5% to 45.81 million ounces compared with 48.00 million ounces at the end of 1971. COMEX stocks declined 37.89 million ounces (33%), and during the same period, the stocks of the Chicago Board of Trade increased by 9.78 million ounces (75%). Industrial stocks declined to 152.46 million ounces compared with 185.34 million ounces at the end of 1971.

Legislation and Government Programs.—There was no legislation pertaining to silver enacted during 1972. Public Law 91–607, enacted December 31, 1970, provided for the minting of 150 million 40% silver, clad Eisenhower dollars during 1971–75 to be sold at premium prices of $10 for proof coins and $3 for others and, in addition, for minting composite cupronickel Eisenhower dollars and Kennedy half-dollars for general circulation. This program proceeded as planned during 1972. In 1972, the Office of Minerals Exploration (OME) of the U.S. Geological Survey negotiated two contracts involving silver totaling $163,620. One prospect is located in the McGrath quadrangle in Alaska, and the other is located in Lander County, Nev. Silver remains one of the minerals eligible for government financial assistance of 75% of the allowable costs of exploration.

DOMESTIC PRODUCTION

Mine output of recoverable silver in the United States was 4.3 million ounces below that of 1971 mainly due to the underground fire in the Sunshine mine in Idaho. Base metal ores provided 75% of the total silver output, and silver ores provided 24%, with the remainder coming from gold and gold-silver production. Idaho's production decreased 26% compared with 1971 production and amounted to 38% of the U.S. production. Total output of silver in Arizona, Colorado, Montana, and Utah remained about the same as in 1971, and the combined production of these four States and Idaho was 86% of the domestic production.

The 25 leading silver producers contributed 85% of the total output. Four of the leading producers (1st, 2nd, 6th and 8th) mined silver ores alone, and the rest were base metal producers. Nine mines produced over 1 million ounces of silver each. Domestic mine output provided almost 25% of the silver consumed by industry and the arts.

In 1972, Hecla Mining Co., Wallace, Idaho, reported the production of 4.47 million ounces of silver, down about 30% from the 1971 output. The average selling price of its silver in 1972 was $1.67 per ounce, as compared with $1.54 per ounce in 1971 and $1.76 per ounce in 1970. Hecla's wholly owned Lucky Friday mine, located in Idaho's Coeur d'Alene district, produced 2.75 million ounces of silver, 19,500 tons of lead, and lesser amounts of zinc, copper, and gold by processing 192,000 tons of ore averaging 14.62 ounces of silver per ton. Ore reserves at the end of 1972 were up nearly 6% to 584,000 tons.

Hecla also owned approximately one-third of the ore produced by the Nation's leading silver producer, the Sunshine mine. During 1972, a major underground fire, which claimed the lives of 91 men, resulted in closure of the mine from May 2 until December 8, 1972. As a result, Hecla's share of the Sunshine production was 33,738 tons of ore assaying 27.32 ounces per ton, compared with 84,212 tons of ore assaying 27.34 ounces of silver per ton in 1971.

In addition to the Sunshine mine, Hecla owns a 30% interest in the Star Unit mine, also located in the Coeur d'Alene district. Hecla's share of production from this property was 208,000 ounces of silver, and substantial tonnages of lead and zinc.

During 1972, Hecla operated the Mayflower mine in the Park City district, Utah, under a leasing arrangement with the New Park Mining Co. Production totaled 114,604 tons of ore assaying 0.46 ounce of gold and 5.95 ounces of silver per ton, 3.22% lead, 2.01% zinc, and 1.35% copper. The mine was closed at yearend, and the agreement with New Park was terminated.

The Galena mine in the Coeur d'Alene district, Idaho, was operated by the American Smelting & Refining Co. (ASARCO). At the Galena mine, under lease from the Callahan Mining Corp., ASARCO produced 4,222,000 ounces of silver from 190,204 tons of ore averaging 22.75 ounces of silver per ton and 0.81% copper.

Kennecott Copper Corp. reported silver production of 4,335,074 ounces in 1972 from processing 58.5 million tons of copper ore. This compared with 3,711,141 ounces produced in 1971 from processing 59.3 million tons of copper ore.

The Bunker Hill Co. produced a total of 3.82 million ounces of silver in 1972, about the same as that in 1971. About 1.53 million ounces of the total was produced at the Crescent mine in 1972 compared with 1.70 million ounces in 1971.

Smelter and refinery reports in 1972 showed that 31.1 million ounces of silver was produced from old scrap and 31.8 million ounces was produced from new scrap compared with 1971 data for old and new scrap of 30.1 million and 16.5 million ounces, respectively. Refinery production, including silver from domestic and imported sources, totaled 140.4 million ounces in 1972 compared with 115.3 million ounces in 1971.

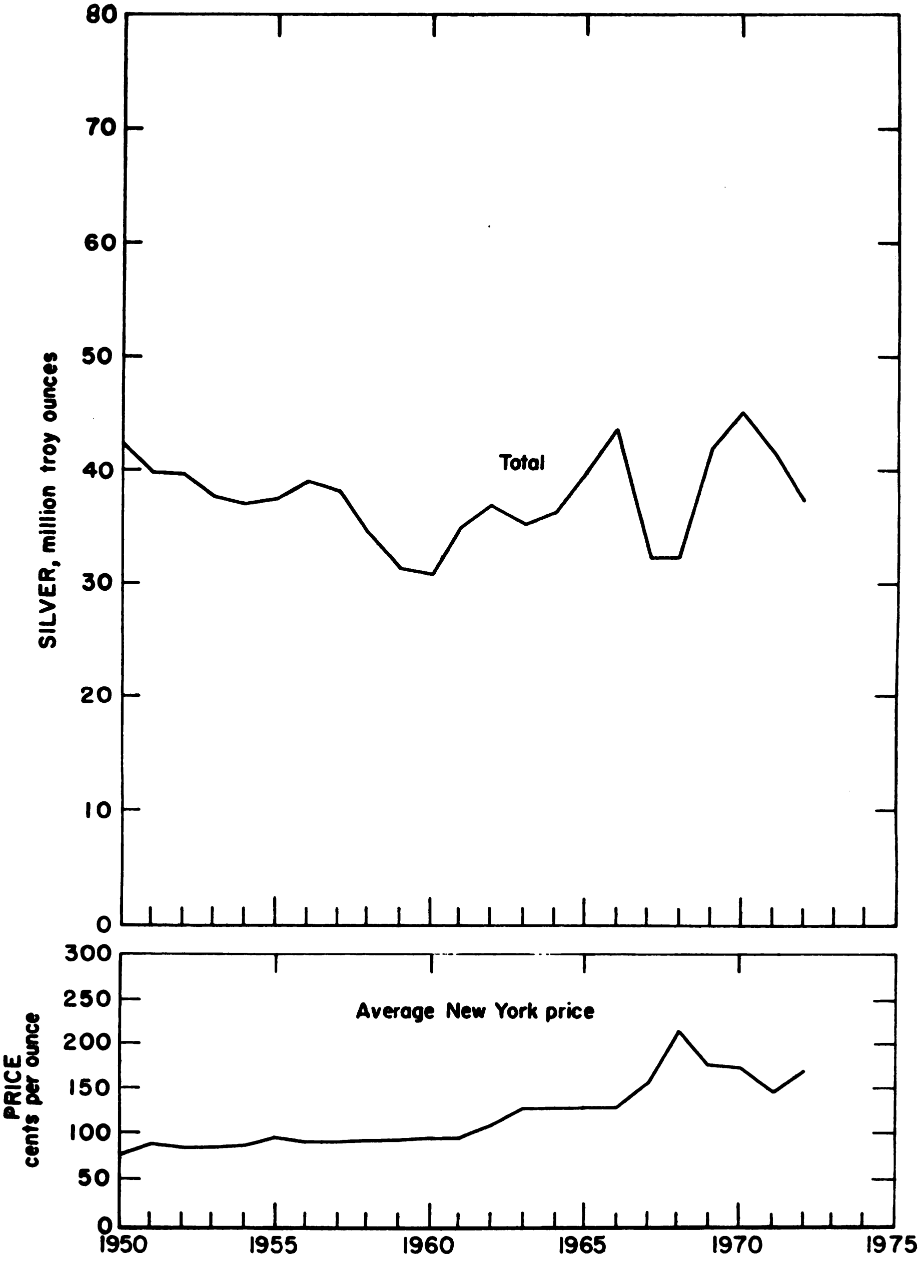

Figure 1.—Silver production in the United States and price per ounce.

CONSUMPTION AND USES

Consumption as measured by sales to consuming industries, compiled by the Bureau of Mines, showed a 17% increase compared with that of 1971. There were significant increases in use in sterling ware, photography, and contacts and conductors. Substantial increases were registered for use in catalysts, jewelry, and electroplated ware, and a large increase in usage was shown for commemorative medals and other collector items, estimated at 11.5 million ounces in 1972 compared with 6 million ounces in 1971. A slight decline was recorded for silver usage in bearings. Photographic materials accounted for about 25% of the total industrial consumption of silver in 1972; contacts and conductors, 24%; sterling ware, 18%; electroplated ware, 8%; brazing alloys and solders, 8%; miscellaneous, 4%; and batteries, 4%. The remaining 9% was used in jewelry, catalysts, dental and medical supplies, mirrors, and bearings.

Use of silver in coinage by the U.S. Bureau of the Mint declined slightly to 2.3 million ounces compared with 2.5 million ounces used in 1971. The silver consumed was used in the production of the 40% silver Eisenhower dollar.

Engelhard Minerals & Chemicals Corp. reported development of a new electrical heating device for defrosting the rear windows of cars. It was installed in some of the 1972 model cars produced in the United States, and more cars are expected to use the device in 1973 and 1974.[2]

A new nonacid silver solder brazing flux was reported to have been developed by Superior Flux & Manufacturing Co.; the flux did not generate free fluorides or other harmful fumes.[3]

STOCKS

The Treasury bullion stock outflow in 1972 totaled 2.3 million ounces, all of which was consumed in U.S. coinage use for the continued production of the Eisenhower silver dollar.

Yearend Treasury stocks were estimated at 45.8 million ounces in bullion, coin bars, and coinage metal fund silver. COMEX silver stocks at yearend 1972 were 77.6 million ounces compared with 115.4 million ounces a year earlier. Chicago Board of Trade stocks at yearend were 22.8 million ounces compared with 13.0 million ounces a year earlier. U.S. Defense Department stocks totaled 8.9 million ounces. Stocks of silver held by refiners, fabricators, and dealers decreased slightly to 52.1 million ounces. Altogether, yearend visible stocks totaled 207.1 million ounces compared with 241.2 million ounces at the end of 1971.

PRICES

Silver prices in New York in 1972, as quoted daily by Handy & Harman, in cents per troy ounce, varied widely, ranging from a low of 138.7 on January 3, 1972, to a high of 204.8 on December 26, 1972. The average price for silver during 1972 was 168.5 cents per ounce in New York.

Prices for spot delivery on the London Bullion Market (U.S. equivalent) ranged from a low of 137.3 cents per ounce on January 3, 1972, to a high of 203.3 cents per ounce on December 29, 1972, and averaged 167.7 cents for the year.

The price rise in the United States was such that by April the market had been brought to within a few cents of a 161.6 cents-per-ounce ceiling price stipulated by the Federal Price Commission as part of price-inflation control measures placed in effect earlier. By July silver prices had exceeded the ceiling price, with the result that a substantial amount of silver was exported. On August 10 the Cost of Living Council exempted silver from price controls. Thereafter, silver prices continued to rise through August but declined in September. In October the market stabilized but then resumed an upward trend throughout the rest of the year and ended December at 204.2 cents per troy ounce.

[3] American Metal Market. New Non-Acid Silver Brazing Solder Flux. V. 79, No. 228, Dec. 13, 1972, p. 6.

Futures trading of silver continued on the COMEX, with the volume for the year at 7.9 billion ounces compared with 6.2 billion ounces in 1971. A monthly record trading of 1.26 billion ounces took place in December. December's closing prices for future delivery, in cents per ounce, were 204.0 (January 1973), 210.5 (September 1973), and 217.4 (May 1974). Silver futures trading was also active on the Chicago Board of Trade, where 3.8 billion ounces were traded in 1972. This was a 52.0% increase over the volume of contracts traded in 1971.

FOREIGN TRADE

Silver exports increased 143% in 1972 to 29.7 million ounces. This compares with 12.2 million ounces exported in 1971. About 37% of the silver exported went to the United Kingdom, 16% went to Switzerland, 16% to France, and 14% went to West Germany. Substantial quantities went to Japan, Belgium-Luxembourg, and Canada. Exports of waste, scrap, and sweepings went mainly to Belgium-Luxembourg, the United Kingdom, and West Germany, and bullion went mainly to the United Kingdom, Switzerland, France, and West Germany.

Silver imports increased in 1972 to 65.4 million ounces, about 13% more than the 58.0 million ounces imported in 1971. The main sources of imports were Canada (50%), Peru (25%), and Mexico (11%), with 21 other countries providing the remaining 14%.

Net imports were 35.7 million ounces in 1972 compared with 45.7 million ounces in 1971.

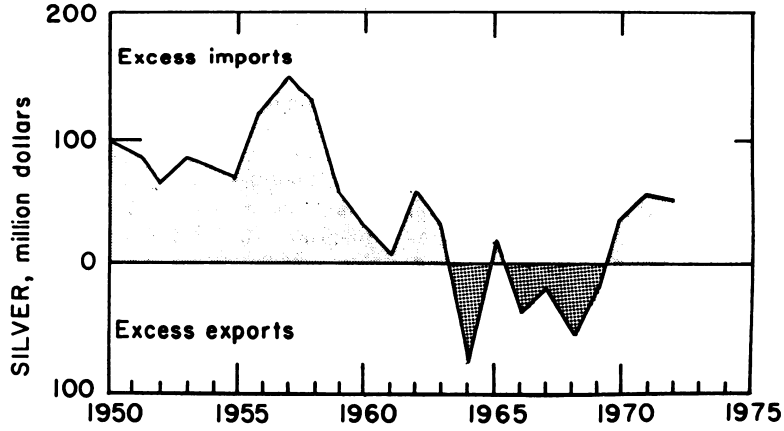

Figure 2.—Net exports or imports of silver, 1950–1972.

WORLD REVIEW

World output of silver amounted to 291.4 million ounces, about 2.5 million more than that of 1971. Peru showed the largest increase and the United States showed the largest drop, owing to the extended closure of the Sunshine mine in Idaho. Increases in production were also reported in Canada and Mexico. Western Hemisphere output of silver provided about 61% of the total world production.

World consumption in arts and industry was estimated at 382 million ounces, up about 22 million ounces over that consumed in 1971.[4] The United States showed the largest increase in consumption, from 129.1 million ounces in 1971 to 151.1 million ounces in 1972. Coinage requirements of silver for the world increased from 27.3 million ounces in 1971 to 40.5 million ounces in 1972. Total free world consumption exceeded production by 90.6 million ounces. This production-consumption gap was met by secondary recovery and from reduction of stocks. Handy & Harman estimated that total worldwide stocks amounted to 366 million ounces.

---

[4] Handy & Harman. The Silver Market, 1972. 57th Annual Rev., 1972, 23 pp.

Canada.—Silver output of Canadian mines increased to an alltime high of 47.0 million ounces of silver in 1972. This was a 2% increase over the 1971 production of 46.0 million ounces and placed Canada again as the leading world producer of silver.

The world's largest single producer of silver, Ecstall Mining Ltd., owned by Texas Gulf Inc., produced 12.8 million ounces of silver in 1972. The silver produced was recovered as byproduct silver in copper, lead, and zinc concentrates from the company's Kidd Creek property, near Timmins, Ontario.

Cominco Ltd., the largest silver producer in British Columbia, derived its output from the lead-zinc-silver ore of its Sullivan mine at Kimberly, British Columbia, and from purchased ores and concentrates. Cominco was also one of Canada's leading producers of refined silver and in 1972 recovered about 5.6 million ounces at its Trail refinery.

Diamond drilling continued at the silver-lead property of Dynasty Exploration Ltd. and Atlas Explorations Ltd. in the Hess Mountain area of the Yukon Territory. Outcrop samples showed good values in silver, lead, and gold.

Agnico-Eagle Mines Ltd. continued an extensive underground development program at its Trout Lake mine in the Cobalt district of northwestern Ontario.

At United Keno Hill Mines Ltd., located near Elsa in the Yukon Territory, production was below that of 1971. In earlier years, this lead-silver-zinc mine was the largest silver producer in Canada. Silver production amounted to 2.5 million ounces compared with 2.9 million ounces in 1971. During the year, the Hector and Calumet mines were idled because of depleted ore reserves; however, potential ore zones were being explored at the nearby Townsite and Dixie properties.

Mill tuneup operations began in August at the 3,000-ton-per-day concentrator of Mattabi Mines Ltd. at its zinc-copper-lead-silver open pit property in the Sturgeon Lake area, 50 miles north of Ignace, Ontario. Ore reserves were reported at 13 million tons grading 7.6% zinc, 0.91% copper, 0.84% lead, and 3.13 ounces of silver per ton.

Dominican Republic.—Gold and Silver reserves on the site of the proposed Pueblo Viejo open pit mine in the Dominican Republic were more than twice what they were thought to be when the project was announced in early 1971, according to New York & Honduras Rosario Mining Co. The project was a joint venture of the New York & Honduras Rosario Mining Co. with J.R. Simplot Co. of Boise, Idaho. The mine was expected to produce 1.5 million ounces of silver and 225,000 ounces of gold per year beginning in 1974. The mine was estimated to have a 20-year reserve at the expected rate of output. Plans were made to construct a cyanide mill to process the ores. Further exploration and studies were to be made of the underlying sulfide zone.

Honduras.—During 1972 the El Mochito mine of the New York & Honduras Rosario Mining Co. supplied 314,476 tons of ore containing 11.72 ounces of silver and 0.009 ounce of gold per ton plus 8.03 lead and 9.37% zinc. The 1972 silver production amounted to 3.4 million ounces, about 3% less than that of 1971.

The exploration and development of the new San Juan ore body was accelerated, resulting in an increase of the reserves by 2.84 million tons. The ore grades 2.6 ounces of silver and 0.002 ounce of gold per ton, 2.68% lead, 6.93% zinc, and 0.32% copper.

Japan.—Mine production of silver in Japan was 10.02 million ounces in 1972, a 11% decrease from the 1971 production. Total consumption rose from 46.0 million ounces in 1971 to 54.4 million ounces in 1972. Refineries produced about 36.1 million ounces of refined silver during 1972. With Peru, Mexico, and Australia as its major suppliers (in that order), Japan imported 16.8 million ounces of silver in refined and unrefined form in 1972. Exports were small, totaling less than 100,000 ounces. Japanese Government stocks of silver were reported to have remained at 16.0 million ounces, unchanged from last year.[5]

Mexico.—Six projects were being explored by two Canadian companies: Tormex Mining Developers and Pure Silver Mines Ltd. (Canada). Possibly the most impressive was the Tormex Industries Peñoles Encantada silver-lead mine in the northern part of the country, 200 miles southeast of Chihuahua. Completion of the 1,000-foot main production shaft was scheduled in 1972. At yearend, proven ore reserves were estimated at 1.5 million tons grading 20 ounces per ton in silver and containing 20% lead. Pure Silver Mines Ltd. (Canada) was also bringing into production three underground mines—the Mother Lode, the Peregrina, and the Cebada—all near Guanajuato, northwest of Mexico City. Total ore reserves were estimated at 4 million tons averaging 11.6 ounces per ton in silver and 0.09 ounce per ton in gold.

The American Smelting & Refining Co. subsidiary, ASARCO Mexicana, S.A., (49% owned by ASARCO) produced 15.5 million ounces of silver during 1972, slightly under the 15.3 million ounces produced in 1971. The mines and plants of ASARCO Mexicana, S.A. operated normally during 1972 with the exception of the Chihuahua lead smelter, which continued to have technical problems. Mine development programs continued during the year. The first phase of the Taxco expansion, consisting of new hoisting and headframe installation, shaft sinking, and preparation of surface sites for the new mill, continued satisfactorily. Cia. Mexicana de Cobre, S.A. continued studies relating to the financing and development of its La Caridad deposit located near Nacozari in the State of Sonora.

Peru.—Cerro de Pasco Corp. smelting facilities at La Oroya, about 118 miles east of Lima, produced 22,991,000 ounces of silver in 1972 (including silver in exported blister copper), of which 58% was from purchased ores. The Cerro de Pasco Corp., a totally owned subsidiary of Cerro Corp., operated six metal mines and their related concentrators, which were located in the central Andean region of Peru. These mines, the Cerro de Pasco, Cobriza, Yauricocha, San Cristobal, Casapalca, and Morococha, produced silver and other metals. At the Cerro de Pasco mine, which produced lead-zinc-silver ore from both open pit and underground operations, 1.9 million short tons of ore was treated per year. The total silver production refined in 1972 at Cerro's Peruvian operations increased about 20% over that in 1971.

United Kingdom.—Net exports of silver in the first 11 months of 1972 were 67.3 million ounces compared with 3.6 million ounces during the similar period of 1971. The principal destinations were Switzerland, which received 30.1 million ounces; Italy, 15.8 million ounces; West Germany, 12.9 million ounces; France, 11.5 million ounces; East Germany, 4.4 million ounces; Austria, 2.8 million ounces; Belgium, 1.0 million ounces; and 3.3 million ounces were sent to miscellaneous other countries. These unusually large amounts of exports from the United Kingdom resulted in a substantial reduction of stocks held in London. Consumption of silver for industrial purposes in the United Kingdom rose about 10% in 1972 to 27.5 million ounces.

TECHNOLOGY

At Bureau of Mines laboratories, work was conducted on the recovery of precious metals from electronic scrap. The objective was to devise an economical process to recover precious metals and copper from low-grade, complex electronic scrap generated in large quantities by military and civilian electronic operations. A process comprising incineration, caustic leaching to remove aluminum, smelting with siliceous slag, and electrolysis produced 99.9% pure copper metal and anode slimes assaying more than 7,000 ounces per ton of combined precious metals. Silver, gold, and copper recoveries were 93%, 95%, and 87%, respectively. Cost analysis indicated that an alternative process using direct smelting of the scrap to make products for sale to a custom smelter would provide better overall financial returns.[6]

Extraction of silver from silver mill tailings by an electrolytic oxidation procedure was investigated.[7] Resulting silver extraction ranged from 77% to 90%, depending on the tailings treated. Power consumption was 52 to 90 kilowatt-hours per ton for the tailings investigated. Silver and mercury were recovered from leach solutions by precipitation on iron powder, followed by conventional distillation and fire refining.

[6] Dannenberg, R. O., J. M. Maurice, and G. M. Potter. Recovery of Precious Metals From Electronic Scrap. BuMines RI 7683, 1972, 19 pp.

The Bureau of Mines investigated sweated aluminum electronic scrap to develop methods for recovering the aluminum and for concentrating the other metals, including copper, lead, gold, and silver, into a product that can be separated by known methods.[8] Two molten-salt electrorefining processes were developed and tested. Over 94% of the aluminum was recovered, and the copper, lead, tin, silver, and gold were concentrated threefold in the anode product. The anode product was smelted to prepare a 96% copper bullion containing 690 ounces of silver and 65 ounces of gold with 98% recovery of these values.

A silver with unusual magnetic properties was a promising organic oxidation catalyst.[9] Discovered by researchers at Britain's Reading University, the material was reported to catalyze the ethylene-to-ethylene-oxide reaction with 15% better selectivity than existing commercial initiators while also showing better activity. It also gave encouraging results for oxidation of propylene and possibly was suited for other oxidations. A number of companies were testing the catalyst. The silver was paramagnetic, whereas ordinary silver is diamagnetic. It was produced by decomposing a compound called silver ketenide (C_2Ag_2O). Its catalytic life was being evaluated.

Table 3.—Mine production of recoverable silver in the United States, by month

(Thousand troy ounces)

Month	1971	1972

e Estimate. p Preliminary. r Revised.

[1] Recoverable content of ores and concentrates produced unless otherwise noted.

[2] In addition to the countries listed Bulgaria, Guatemala, Thailand, Turkey, and several other African countries produce silver, but quantities are insignificant or not reported.

[3] Production by the state Mining Company (COMIBOL) plus exports of medium and small (private sector) mines.

[4] Smelter and/or refinery production.

[5] Series revised to indicate mine output; previous data represented metal production.

[6] Output of Inyati mine only.

[7] Recoverable content of Tsumeb Corp. Ltd. concentrates, as reported for year ending June 30 of 1970 and 1971. Data for 1972 represent calendar year production; production of silver for last 6 months of 1971 was 649 thousand troy ounces.

[8] Includes recovery from copper refinery sludges.

Slag—Iron and Steel

By Harold J. Drake[1]

Production of processed iron and steel slag was up 6% in 1972 in contrast to the slight decline that occurred in 1971. The advance was led by a 20% increase in production of steel slag and a 1% increase in output of iron slag. A small rise in output of air-cooled iron-blast-furnace slag, which normally accounts for about 85% of iron slag, was partly offset by declines in output of other types. Increased consumption of iron and steel slag was reported in most of its principal uses.

Prices of iron slag generally were stable in 1972; only slight increases were recorded in principal uses. The average price of all steel slag declined. Imports were off again by 37% whereas export tonnage rose significantly by 27%. Value of exports declined sharply, principally because of sharply reduced shipments of high-value material to Belgium-Luxembourg.

DOMESTIC PRODUCTION

Production of iron and steel slag in 1972 totaled 35.2 million tons valued at $64.4 million. In terms of quantity, production was up 6%. The 8% increase in value was partly accounted for by the inclusion in 1972 of the value of slag used in manufacturing hydraulic cement. Output of iron-blast-furnace slag rose slightly to 25.1 million tons valued at $53.4 million, while that of steel slag totaled 10.2 million tons valued at $11 million.

Screened, air-cooled iron slag in recording a 4% increase in output to 21 million tons valued at $43.7 million, accounted for 84% of the total slag output. Unscreened, air-cooled iron slag, granulated iron slag, and expanded iron slag again recorded declines in output tonnage. The increases in value reported for granulated and expanded slags were due to the inclusion in 1972 of the value of slag used in the manufacture of hydraulic cement.

Production was reported in 16 States; Pennsylvania led, followed by Ohio, Illinois, Indiana, and Michigan. These five States again accounted for two-thirds of domestic output. In 1972, there were 90 plants producing air-cooled slag, 16 producing expanded slag, and 12 producing granulated slag. A total of 1,685 production employees worked 3,757,033 man-hours during the year. The quantity of slag-encrusted magnetic iron recovered at slag plants totaled 3,692,000 tons.

CONSUMPTION AND USES

Construction uses dominated the market for slag in 1972. In the aggregate, use for construction purposes totaled 16.5 million tons valued at $35.6 million, up 8% from

the preceding year. The principal market for air-cooled iron slag, highway and airport construction, expanded about 6%, while the next largest market, bituminous construction, rose 11%. Use in portland cement construction recorded a 5% decline. In nonconstruction uses, railroad ballast recorded a 16% gain, and use in mineral wool, a 71% gain.

Consumption of granulated slag at 1.7 million tons valued at $3.1 million was off 7%, and that of expanded slag at 1.5 million tons valued at $5.5 million was off 4%. The only use of these slags recording an increase in 1972 was that of cement manufacture. The use of granulated slag in highway construction, the principal use, was off slightly. Nearly all expanded slag was used in the manufacture of concrete block, and in 1972, consumption therein was off 6%.

Consumption of steel slag, continuing the trend of recent years, was up as the construction industry continued to use greater quantities. Consumption reached 10.2 million short tons valued at $11 million. Use in highway construction soared 36%, to 3.6 million tons valued at $3.5 million, and use as base material in paved areas was up 60% to 1.8 million tons valued at $1.8 million. Use as railroad ballast rose 55%; miscellaneous base and fill uses declined 6%.

PRICES

The average unit value for all iron-blast-furnace slag in 1972 was $2.13 per ton, nearly the same as in the preceding year. The average unit value for all steel slag fell from $1.14 per ton in 1971 to $1.08 per ton in 1972.

Although sizable changes in unit values occurred by uses, variations in the principal uses were minor, reflecting price controls that existed in 1972. Unit values of bituminous construction and highway and airport construction slags were up 3 cents per ton, portland cement construction slags, 10 cents per ton, and railroad ballast slags, 4 cents per ton.

Due to the inclusion of the value of slags used in the production of hydraulic cement in 1972, price comparisons with 1971 on granulated and expanded slags are not possible. Unit values of steel slags, in general, declined slightly except for many minor uses which rose slightly.

FOREIGN TRADE

U.S. exports of iron and steel slag, dross, and scalings in 1972 totaled 27,491 short tons valued at $205,132. Sharp annual fluctuations in tonnage and value of slags exported to Belgium-Luxembourg, Bermuda, Canada, and Colombia, the principal foreign markets for slags, preclude comparisons with preceding years. Imports, all from Canada, totaled 1,455 tons valued at $16,867 compared with 2,324 tons valued at $27,050 in 1971.

Table 8.—U.S. exports and imports for consumption of slag, dross, and scaling from the manufacture of iron and steel

Sodium and Sodium Compounds

By Charles L. Klingman [1]

Production of sodium compounds from natural sources, trona and dry lakes and well brines, accounted for practically all the increased sodium output in 1972. Soda ash (sodium carbonate) made from natural sources increased 12.3% compared with the output from this source in 1971. On the other hand, soda ash manufactured from salt by the Solvay process increased only 0.6% compared with 1971 output. Salt cake made from brine increased 1.9% compared to an equal decline in output of manufactured sodium sulfate. Several manufacturers of naturally derived sodium compounds completed sizable increases in their production capacity in 1972 and announced plans for further increases through 1975.

Metallic sodium also showed a small increase in production. Most of it was consumed in the manufacture of tetraethyl and tetramethyl lead, compounds used as gasoline additives. Despite proposed stringent standards for air pollution from automotive exhausts, the expected decreases in the use of these compounds failed to materialize.

DOMESTIC PRODUCTION

In 1972 total soda ash production increased 5.3% over that of the previous year as compared with a 2.7% per year average growth rate since 1958. Practically all the 1972 growth occurred in natural soda ash. The portion of the total ash production, which came from natural origins, increased from 40.1% in 1971 to 42.8% in 1972. The average unit value of natural soda ash reported by producers, increased 5.0%, and the total value of the 1972 natural soda ash output increased 18.0% above comparable figures in 1971.

Total sodium sulfate showed no change in output. In a trade-off, the manufactured product declined and the natural product increased 1.9% compared with 1971 figures. The fraction of sodium sulfate derived from natural sources crept up from 50.7% to 51.6% of the total.

Metallic sodium production increased 4.5% over that of 1971 to a total of 159,881 short tons.

[3] Includes glauber salt.

In 1972 FMC Corporation added another unit capable of producing 500,000 tons of soda ash per year to its existing facilities at Green River, Wyo. This raised the capacity of this plant to 1.75 million tons per year. Future expansion of 750,000 more tons per year is planned.

Stauffer Chemical Co. also completed a 500,000 ton per year expansion in its Wyoming soda ash production capacity and planned further expansion.

Allied Chemical Corp. was in the process of doubling its production capacity to 1.1 million tons per year and planned to double this figure again by 1974. At present approximately 1,500 people are employed by the three soda ash producers in Green River, Wyo.

A fourth company, Texas Gulf, Inc., announced intention of opening a trona mine and soda ash processing plant in the vicinity of Green River, Wyo. Its planned capacity was 1 million tons per year.

At Searles Lake in California, Kerr-McGee Corp. announced plans for expansion of its present soda ash facilities by 1 million tons per year. Large-scale experimentation with evaporites from Searles Lake was also being conducted by Garrett Research and Development Co., with the intention of opening a new facility for production of soda ash and other chemicals from the lake brine. The plant was expected to be operated by Occidental Petroleum Co.

All three soda ash plants in Green River, Wyo., were cut off from heating gas during a period of prolonged cold weather. Stauffer and FMC obtained permission from the Public Service Commission to build their own pipelines to the Baxter and Bird Canyon Gas Fields so they would be independent of the local gas network which has primary obligations to residences and public buildings.

The final shutdown of the PPG Industries, Inc. Solvay soda ash plant at Barberton, Ohio, was not completed in 1972 as planned because of a temporary high demand for the carbonate. As of the end of 1972 there were six companies operating eight synthetic soda ash plants in five States with a total reported production capacity of 4.65 million tons per year. There are no known plans to close any of these Solvay plants except the PPG plant in Barberton, Ohio.

A list of U.S. producers of natural sodium compounds and metallic sodium is presented in the following tabulation:

Product	Company	Plant Location	State	Source of sodium
Soda ash	Kerr-McGee Chemical Co	Trona	California	Dry lake brine.
Do	Stauffer Chemical Co	do	do	Do.
Do	Allied Chemical Corp	Green River	Wyoming	Underground trona.
Do	FMC Corp	do	do	Do.
Do	Stauffer Chemical Co	do	do	Do.

Do	do	Memphis	Tennessee	Do.
Do	Ethyl Corp	Baton Rouge	Louisiana	Do.
Do	do	Houston	Texas	Do.
Do	Reactive Metals Inc	Ashtabula	Ohio	Do.

CONSUMPTION AND USES

Nearly half (47%) of the soda ash production in 1972 was consumed in making glass; 25% went to making other chemicals such as sodium bicarbonate; 7% to the pulp and paper industries; 6% to cleaning agents; 3% to water treatment; and the remaining 12% was consumed in miscellaneous uses. Reduction in the use of phosphates in detergents caused a slight increase in soda ash as replacement material.

About 67% of all sodium sulfate production in 1972 went to the making of paper pulp and Kraft paper, but continuing technological changes in the pulp industry may cause a reduction in this usage in the future. About 18% of the sodium sulfate production went to the manufacture of various detergents, and the remaining 15% went to a variety of uses such as glass, stockfeeds, dyes, textiles, and medicines.

The major use for metallic sodium continued to be the manufacture of tetraethyl and tetramethyl lead antiknock compounds for gasoline. About 83% went to this end use in 1972. Four percent of the sodium metal was used to reduce other metals, such as titanium, and the remaining 13% went to miscellaneous uses such as the making of soap and detergents, dyes, explosives, and agricultural chemicals.

The Intergovernmental Relations Subcommittee of the House of Representatives accused the Food and Drug Administration and the U.S. Department of Agriculture of failing to protect the public from excessive use of sodium nitrate and sodium nitrite in meats and other food.[2] Experiments have indicated that the nitrite in food may be chemically converted to nitrosamines, which are known to be potent promoters of cancer in animals and possibly also in human beings.

A lawsuit has also been filed against the Secretary of Agriculture by the Center for Science in the Public Interest, and others, to prohibit the use of nitrates and nitrites in human food. The use of sodium nitrates or sodium nitrites in foods does not constitute a large market, but it is possible that this usage may soon be illegal.

PRICES

Market prices quoted at yearend for sodium carbonate, sodium sulfate, and metallic sodium were as follows:

		1971	1972 [1]
Sodium carbonate (soda ash):			
Light, paper bags, carlots, works	per 100 pounds	$2.35	$2.47½
Light, bulk, carlots, works	do	1.65	1.77½
Dense, paper bags, carlots works	do	2.40–2.45	2.47½
Dense, bulk, carlots, works	do	1.65–1.80	1.77½
Sodium sulfate (100 percent Na_2SO_4):			
Technical detergent, rayon-grade, bags, carlots	per ton	40.00–43.00	43.00–46.00
Technical detergent, rayon-grade, bulk, works	do	33.00–34.00	33.00
Domestic salt cake, bulk, works [2]	do	28.00	28.00
National Formulary (N.F. XII), drums	per pound	.23½	.23½
Metallic sodium:			
Bricks, carlots, works	do	.30	.30
Fused, lots 18,000 pounds and more, works	do	.26½–.27½	.26½–.27½
Bulk, tank, works	do	.18¾	.18¾

[2] Delivered east of the Mississippi River.

FOREIGN TRADE

In 1972, exports of sodium carbonate increased 10% in tonnage and 23% in value over comparable data for 1971. The fraction of soda ash production exported, however, was 6% which remained about the same as that of the previous year. Canada received 53% of the export; Argentina about 15%; and Venezuela 9%. The remaining 23% was widely distributed to various countries mostly in South America and Asia.

Imports of sodium sulfate increased 12% in tonnage and 15% in value over those of

Table 3.—U.S. exports of sodium carbonate and sodium sulfate

(Thousand short tons and thousand dollars)

Year	Sodium carbonate		Sodium sulfate	
	Quantity	Value	Quantity	Value
1970	336	12,007	55	1,668
1971	437	15,400	66	1,825
1972	480	18,914	29	926

1971. Exports of sodium sulfate were less than half of those of 1971. The net imports (imports less exports) amounted to 39% of the total U.S. sodium sulfate consumption. Canada supplied 44% of the sodium sulfate imports, and Belgium-Luxembourg supplied an equal amount. Netherlands, West Germany, and Sweden provided the remainder.

The value of exports of sodium compounds exceeded the value of imports by $14.5 million.

Tariff rates for sodium compounds remained constant throughout the year as shown in the following tabulation:

	Tariff: (dollars per short ton)	
	January 1, 1972	January 1, 1973
Sodium carbonate:		
Calcined (soda ash)	2.40	2.40
Hydrated and sesquicarbonate	2.00	2.00
Sodium sulfate:		
Crude (salt cake)	Free	Free
Anhydrous	.25	.25
Crystallized (glauber salt)	.50	.50

Table 4.—U.S. imports for consumption of sodium sulfate

(Thousand short tons and thousand dollars)

Year	Crude (salt cake) [1]		Anhydrous		Total [1]	
	Quantity	Value	Quantity	Value	Quantity	Value

1971	236	4,108	r 32	559	r 268	4,667
1972	226	4,082	73	1,275	299	5,358

r Revised.

[1] Includes glauber salt as follows: 1970 and 1971, none; 1972, 50 long tons ($1,491).

WORLD REVIEW

Argentina.—The Government of Argentina finally approved the building of a Solvay soda ash plant in the Province of Rio Negro.[3] The plant was designed to have a capacity of 220,000 short tons per year and will cost approximately $35 million. The new plant was predicted to produce soda ash for about $62 per short ton. This may be compared to average U.S. production costs of $35 per short ton. There will be a minimal chance of exporting soda ash under such conditions.

Brazil.—In 1971, the government-owned corporation of Brazil, Companhia Nacional de Alcalis, produced 204,000 short tons of synthetic soda ash, which was about 93% of the installed capacity.[4] In 1972 the government contracted the building of additional facilities to increase total soda ash production to about 240,000 short tons per year.[5]

Canada.—A soda ash plant in Amherstburg, Ontario, operated by Allied Chemical Corp., is being expanded from a capacity of 375,000 to 485,000 short tons per year. The construction should be completed by 1975.[6]

Exports of sodium sulfate from Canada increased 7% in tonnage and 5% in value in 1972 as compared to the 1971 export figures.

Germany, West.—Soda ash production in Germany was reported to be 1,486,000 short tons in 1971.[7]

Italy.—Two Italian chemical companies, Orinoco S.p.A. and Ente Minerario Siciliano, joined forces to build a new chemical plant at Termini Imerese, Sicily. It was designed to produce 473,000 short tons per year of both light and dense soda ash by mid-1973. The facility is expected to create 1,100 new jobs.[8]

[7] U.S. Embassy, Duesseldorf, Germany. State Department Airgram, A-90, June 19, 1972, p. 1.

Sofos S.p.A. (Orinco S.p.A.) is building a new plant in Palermo, Sicily, designed to produce 44,000 short tons per year of sodium and potassium sulfates by 1973.[9]

Spain.—One of the major synthetic soda ash production centers of the world at Torrelavega, Spain, was being increased from 420,000 to 770,000 short tons per year. Expenditures for the expansion was about $12 million.[10]

Sweden.—A soda recovery plant at a pulp mill has been ordered in Bruk, Sweden, to be completed by the end of 1973. The recovery plant features a membrane wall and has a capacity of 564 short tons per day of dry substance.[11]

TECHNOLOGY

A new process for making synthetic soda ash at low cost and without pollution has been described[12] by two scientists from Oak Ridge National Laboratory and the University of California. The proposed system is similar to the traditional Solvay process except that the ammonium chloride produced is reconverted to ammonia by the use of magnesia instead of limestone. The magnesium chloride thus formed is recycled to its original state, magnesia, by heating to about 550° C and in so doing produces hydrogen chloride as a salable byproduct. There is no calcium chloride to be disposed of, and the salt entering the reaction is completely utilized in the process. The developers concede that the proposed process presents little economic threat to soda ash derived from naturally occurring trona; but in Europe, Japan, or other industrial countries the new process may be competitive with the existing Solvay plants.

Stone

By Harold J. Drake [1]

Production of stone increased 5% from 876 million tons in 1971 to 924 million tons in 1972. Total value increased to a new high of $1.7 billion. Crushed stone accounted for more than 99% of the total volume produced, but its value was only 95% of the total value. Production of crushed stone was 922 million tons valued at $1.6 billion compared with 874 million tons valued at $1.5 billion in 1971. The main uses of crushed stone were dense-graded road-base stone, 23%; concrete aggregate (coarse), 14%; cement manufacture, 12%; unspecified construction aggregate and road stone, 12%; and bituminous aggregate, 9%. Output of dimension stone totaled 1.5 million tons valued at $90.8 million. Dimension stone accounted for less than 1% of total stone output.

Production of stone was reported in all States except Delaware. Pennsylvania, with a total stone production of 67 million tons, was the Nation's leader. Other large producers, in order of output, were Illinois, Florida, Texas, Ohio, and Missouri. These six leading States produced 317 million tons, or 34% of the Nation's output.

Prices of stone generally were stable in 1972; small increases were recorded for some types of stone. The average unit value of all stone increased somewhat. In terms of value, imports were up 29%, whereas exports declined 3%.

Legislation and Government Programs.—The United Steelworkers of America on behalf of workers of the Vermont Marble Co. plant at Rutland, Vt., filed a petition requesting certification of eligibility to apply for adjustment assistance. The request was made under the President's decision of January 28, 1972, pursuant to Sec. 302 (A) (3), of the Trade Expansion Act of 1962, that workers in the domestic marble and travertine industry were eligible to apply for adjustment assistance, under chapter 3, Title III of this act.

The Environmental Protection Agency (EPA) continued to study dust emissions from aggregate-producing facilities and related plants. Dust emission standards are being developed and were expected to be implemented in the not too distant future.

DIMENSION STONE

DOMESTIC PRODUCTION

Production of dimension stone in 1972 decreased about 8% in quantity and 3% in value from the levels of the preceding year. Production totaled 1.5 million tons valued at $90.8 million.

Output of dimension granite in 1972 totaled 621,000 tons valued at $42.6 million, increases of 8% and 11%, respectively, from those of 1971. Production of limestone and dolomite was off 12% in quantity and 5% in value. Production of marble declined to 71,000 tons valued at $16.5 million. Production of sandstone, quartz, and quartzite totaled 231,000 tons valued at $7.7 million compared with 332,000 tons valued at $10.1 million in 1971. Slate production was down 15% from that of 1971.

Domestic production of rough dimension stone totaled 850 thousand tons valued at $23.1 million. Of this quantity, 34% was accounted for by monumental stone, 34% by architectural stone, 28% by construction stone, and 4% by flagging. Less than 1% was accounted for by miscellaneous uses. Production of dressed stone totaled 642,000 tons valued at $67.7 million. About 28% of this was cut and sawed, 20% was curbing, and 17% was house stone veneer. The remainder consisted principally of flagging, monumental, and construction stone. In terms of value, however, the principal dressed stone varieties were cut stone and monumental stone.

CONSUMPTION AND USES

Apparent consumption of dimension stone in 1972 was valued at $125 million, 6% higher than in 1971. Almost all the increase was accounted for by increased imports. Consumption of domestically produced dimension stone in 1972 was lower than in the preceding year. Tonnage of stone used in 1972 compared with 1971 was as follows: granite, up 8%; limestone, down 12%; marble, down 5%; sandstone, down 30%; slate, down 15%; and miscellaneous stone, down 1%.

In terms of value, apparent consumption of granite, which accounted for about two-fifths of total dimension stone consumption in 1972, totaled $52 million, up about 13%. Consumption of marble totaled $32.6 million compared with $30.2 million in 1971. Consumption of limestone, sandstone, and quartzite, in total, was 13% below the levels of 1971.

PRICES

Delivered prices of dimension stone are dependent upon stone variety, finished form, and market location and are not reported to the Bureau of Mines. Average unit values for dimension stone in 1972, as reported to the Bureau of Mines, are as follows, in dollars per ton:

	Building		Monumental, rough and dressed	Flagging
	Rough	Dressed		
Granite	28.01	--	66.85	--
Marble	48.22	259.79	--	--
Limestone	21.28	57.11	--	13.67
Sandstone	12.81	55.14	--	--
Slate	--	174.37	--	31.83
Miscellaneous	13.81	130.78	--	--

FOREIGN TRADE

U.S. exports of dimension stone were valued at $3 million, a level about 22% below that of the preceding year. Approximately one-third of the exports was dolomite, one-half of which was sent to Canada. Nearly all of the remainder was sent to Central and South America. Exports of monumental and building granite were valued at $652,000, nearly all of which was sent to Canada and Japan. Approximately two-thirds of the slate exports consisted of roughly split, squared, or sawed material and one-third consisted of worked slate. Canada again was the principal recipient of this material. Exports of miscellaneous, building, and monumental stone totaled $1.2 million. Canada received 63% of this material; the remainder went principally to Mexico, Japan, Brazil, West Germany, and France.

U.S. imports of dimension stone in 1972 totaled $34.2 million compared to $26.6 million in 1971. Marble accounted for about 47%; granite, 27%; slate, 17%; and travertine, 9%. Imports of marble were valued at $16.1 million, a 27% increase over the level of the preceding year. Imports of granite rose 23% to $9.4 million, and imports of travertine stone were up 12% to $3 million. Imports of slate sharply increased to $5.7 million compared with $3.4 million in 1971. Principal import items were marble slabs and paving tiles valued at $8.4 million, dressed granite articles valued at $7.6 million, slate articles valued at $5.7 million, and dressed travertine valued at $2.8 million. Tonnage of rough blocks of marble and granite was well below that of the preceding year, whereas that of travertine nearly doubled.

Italy and Portugal again supplied the great bulk of the marble and travertine imports. Canada and Italy accounted for most of the imported granite. The remainder was supplied by numerous small countries.

WORLD REVIEW

Argentina.—One of the world's largest deposits of black granite has been reportedly found in Mendoza Province. The granite is said to be of excellent quality and, on the surface, occurs as flagstone, which can be exploited without the need for cutting.

Canada.—Production of dimension stone consists principally of granite, limestone, marble, and sandstone. Approximately 80% of the output is used in construction; the remainder is used as monumental or ornamental stone. Granite, limestone, and marble are used in the form of cut and polished panels in institutional and commercial buildings; limestone and sandstone are used as ashlar in residential buildings.

Portugal.—Portugal continued to be one of the world's largest dimension stone producers. In 1971 total production of dimension stone exceeded 9.4 million short tons, 72% of which was limestone and 19% was granite. The remainder consisted of marble, slate, and miscellaneous stone such as diorite and gabbro. Large volumes of rough stone are exported to Italy where they are processed and eventually reexported.

CRUSHED STONE

DOMESTIC PRODUCTION

Production of crushed stone reached an alltime high of 922 million tons valued at $1.6 billion in 1972. The advance was led by a 7% increase in the output of limestone and dolomite to 671 million tons valued at $1.1 billion and a 14% increase in the output of granite to 106 million tons valued at $183 million. Production of traprock totaled 80 million tons valued at $171 million, an increase of 7% over the levels of 1971. Output of marble was up 37% to 2.2 million tons valued at $25 million. Offsetting the increased production of these kinds of stone were declines in the production of marl, sandstone, shell and other kinds of stone. Output of sandstone decreased 12% to 27 million tons valued at $58 million, output of shell decreased 10% to 17 million tons valued at $30 million, and other stone declined 38% to 14 million tons valued at $24 million. Five States, Florida, Illinois, Ohio, Pennsylvania, and Texas, accounted for one-third of the total production of crushed stone in 1972. With the exception of Illinois each of these States recorded increased output. The largest output was recorded by Pennsylvania, which increased its output 4% to 67 million tons valued at $120 million. In 1972, 14 States accounted for two-thirds of the total production of crushed stone.

Domestic producers during 1972 were concerned with rising labor and maintenance costs accompanied by price controls, depletion of raw material, and pollution control. Control of dust emission was the primary problem, although many companies were also required to treat process water and to reduce noise. It is believed that more than half of the U.S. producers of crushed stone now control dust emissions. Of interest to aggregate producers was the dust-collection system installed by an asphalt producer, Hills Materials Co., Rapid City, S. Dak.[2] A new bag system collector was installed following a cyclone collector used to return coarser dust particles to the mix. The new system collected more than 99% of the fines, which were either returned to the system or sold at an advantageous price. The principal market for the collected fines was as a mineral filler, which contributed to the company's revenues. Of equal importance was the goodwill generated in neighboring residential areas by the complete elimination of airborne dust.

---

[2] Roads and Streets. Asphalt Plant Solves Dust Problem, Makes Valuable By-product. V. 115, No. 7, July 1972, pp. 97–101.

Anticipated increased demand in the near future led to the expansion of current facilities and the addition of a number of new plants in 1972. General Crushed Stone Co., Easton, Pa., doubled the capacity of its Rockhill quarry located near Quakertown.[3] The company plans to add an automated bituminous concrete plant to the facility. U.S. Steel Corp. recently completed its second year of stone production from its modernized and rehabilitated Calcite Plant at Rogers City, Mich.[4] Increased demand for metallurgical limestone for the company's own needs and to meet expanding growth in chemical and other industrial markets led to the expansion. Principal changes that occurred included expanded screening and crushing capacity and the replacement of stationary stockpiling conveyors with several traveling stackers.

An article described the action of surfactants on water and the action of the combined surfactant and water in dust suppression. Surfactants were used to lower the surface tension of water and thereby increase its ability to agglomerate dust particles to prevent them from becoming airborne.[5]

Depletion of local sand and gravel deposits caused aggregate producers to switch to crushed stone production. One company developed a granite deposit to supply aggregate to its ready-mix concrete operations and to its asphalt plant.[6] The company fortunately was able to use much of the equipment from its discontinued sand and gravel operations. Another granite deposit was also developed to supplement diminishing supplies of gravel.[7] This granite deposit will be used as coarse aggregate to supplement sand and gravel operations that are rich in sand but short on gravel.

A new sandstone quarry in Pennsylvania was in full operation in 1972.[8] The quarry is located at Elysburg, Pa., and produces crushed sandstone for road-base material and ready-mix concrete in the Mt. Carmel-Shamokin area. Another relatively new aggregate producer, Specifications Stone Co., Pana, Ill., has been successful in producing a premium material for a premium market.[9] In operating the limestone quarry, the company has been able to produce a premium material to supply aggregate markets that are more than twice the average shipping distance usually found in the crushed stone aggregates industry.

Staying competitive is a problem faced by most aggregate producers. Companies usually meet the problem by acquiring bigger loaders, trucks, and screens; by using portable plants; by strategically locating stockpiles; and, by using portable overland conveyor systems. Bruening Rock Products, Inc., Decorah, Iowa, used two portable crushing and screening plants and much larger front-end loaders to produce crushed stone from 26 different locations.[10] In addition, the company uses larger haulage trucks to ship farther and faster in order to widen its marketing area.

A large portable, impact crusher mounted on a mobile frame containing a vibratory feeder and diesel engine drive helped another aggregate producer remain competitive.[11] The quarry produced crushed limestone at a rate of more than 600 tons per hour, 24 hours per day to yield six sizes. In order to do so, the crusher unit had to have a very high degree of mobility and a low input of oversize rock. Harrison, Inc., Alcoa, Tenn., operated a granite quarry at Franklin, N.C., using portable aggregate processing equipment with remarkable flexibility in volume of output and in the variety of products produced.[12] Complicating the operation was the fact that no sand existed in the area, thus requiring a sand preparation system to produce sand from crushed granite.

Unusual capacity and product sizing flexibility resulting from a large new portable secondary crushing and screening plant gave the Joe Boulanger Construction Co., Fond du Lac, Wis., a strong competitive position.[13] The strategic location of a granite-gneiss aggregates quarry serving a large metropolitan area allowed an asphalt contractor, Tri-County Asphalt Corp., Roseland, N.J., to sharply expand its operation and to diversify into paving and heavy construction.[14] The company used foresight in acquiring its aggregate resource several years before zoning laws, traffic ordinances, and clean air regulations were extended into northern New Jersey thus severely restricting the development of new quarries.

A specially designed suspension span-conveyor system was used to transport crushed stone across a river from the quarry to marketing areas.[15] The deep-trough conveyor was suspended over the river and carried material reduced and dry-screened to specification sizes. Ripping was again proven to be a useful tool for aggregate producers.[16] As a result of instituting a ripping system, production was boosted, costs lowered, and potential trouble with residents in nearby areas was avoided. Ripping costs were less than half the drilling and blasting costs and, since ripping produced better fragmentation, the amount of secondary breakage required was sharply reduced.

CONSUMPTION AND USES

Apparent consumption of crushed stone in 1972 totaled 923 million tons valued at $1.6 billion, an increase of 6% in quantity and value over that of the preceding year. Consumption was higher for most kinds of crushed stone. Compared with the preceding year, limestone and dolomite, which accounted for 73% of the total consumption, rose 7%; traprock, 9% of total consumption, rose 7%; and granite, 12% of total consumption, rose about 14%. Consumption of crushed marble rose 37%. Consumption of sandstone declined about 12%, shell about 10%, calcareous marl about 23%, and miscellaneous stone about 38%.

The principal use for crushed stone of all kinds was as an aggregate in construction, and in paving. Approximately 667 million tons valued at $1.1 million was used for these purposes. The major uses of aggregates were as road-base stone, which rose 10% to 210 million tons valued at $337 million, and concrete aggregate, which dropped 1% to 133 million tons valued at $228 million. Other uses recording production gains were bituminous aggregate, up 4%, and unspecified construction aggregate and road stone, up 17%. Use of crushed stone in the production of cement rose slightly to 109 million tons valued at $130 million, and agricultural purposes declined 16% to 28 million tons valued at $65 million. Stone used in the manufacture of lime declined 1% to 30 million tons valued at $49 million and that used as a flux rose to 26 million tons valued at $45 million.

A two-part series on calcium carbonate —natural chalk whiting, ground limestone, and precipated calcium carbonate—was published. The first part dealt with the different varieties and properties of calcium carbonate fillers (including mining and treatment) and the physical and chemical data of typical calcium carbonate fillers.[17] The second part dealt with patterns of consumption and examined in detail important consuming industries such as paint, putty, rubber, plastics, and paper. In addition, international trade and prices were discussed and an appraisal of future prospects for the calcium carbonate filler-extender industry was given.[18]

PRICES

Quotations in Engineering News-Record for carload lots of 1½-inch crushed stone in 1972, exclusive of discounts, ranged from $6.60 per ton in Los Angeles to $1.60 per ton in Birmingham. The average price reported for 12 major cities was $3.39 per ton. Prices for ¾-inch crushed stone ranged from $1.50 per ton in Minneapolis to $1.65 per ton in Birmingham. The average price for 12 major cities was $3.47 per ton. Prices per ton for industrial fillers and extenders, as reported in the American Paint Journal, were as follows, in dollars:

FOREIGN TRADE

Exports of crushed stone totaled 2.8 million tons valued at $8.1 million in 1972, a slight increase over that of 1971. A decline in exports of crushed limestone was offset by increased exports of other kinds of stone. As in past years, Canada was the principal export market, although some smaller quantities were shipped to other countries in North America.

Imports of crushed stone supplied only a very small share of the U.S. market and in 1972 recorded a 27% increase to 3.2 million tons valued at $4.7 million. Imports of crushed limestone, for use principally in the manufacture of cement, rose 19% to 1.9 million tons valued at $2.6 million; imports of other crushed stone rose 41% to 1.3 million tons valued at $2 million. Imports of dry-ground whiting recorded a modest gain to 20,782 short tons valued at $621,000; imports of precipated chalk whiting rose slightly to 1,895 short tons valued at $150,000.

WORLD REVIEW

Belgium.—Crushed stone production for aggregate use in Belgium in 1971, the latest year for which detailed statistics are available, totaled 31.2 million tons. Approximately 58% of this quantity was accounted for by limestone and 26% by porphyry; the remainder consisted of sandstone and miscellaneous stone. In addition to extensive deposits of igneous rocks in Belgium, local deposits of limestone, quartzite, marble, and sandstone are being worked in many areas.[19] Chalk for use in the cement industry is mined extensively. The largest quarry in Belgium is operated by S. A. Compagnie des Ciments Belges near Tournai. The quarry can produce crushed limestone at a rate of 35,000 tons per day.

Canada.—Capacity of a limestone quarry on Texada Island, northwest of Vancouver, British Columbia, will be more than doubled by a $4 million project scheduled for completion by the early fall of 1973.[20] When completed, the facility will have a capacity of 3.6 million tons of limestone per year, and a 4,000-foot conveyor belt to transfer the crushed stone to ocean-going vessels. A cantilevered swinging boom will be used to load the vessels in any part of the anchorage.

India.—Granite rocks of the Ranikhet area in Uttar Pradesh were described.[21] The study complements previous studies of granitic rocks of the Central Himalayas and is based on field, laboratory, microscopic, and chemical studies.

U.S.S.R.—The Turgoyaksk limestone quarry produced and processed flux stone for use in the Southern Urals metallurgical works. Of the two production systems used, one transports the broken ore by locomotive to the crushing and grading plant and the second uses a 330-ton-per-hour mobile crushing and grading rig. A third system utilizing a large mobile rotary crusher-grader with a capacity of 1,100-tons-per-hour is planned. All three systems make extensive use of belt conveyors.

United Kingdom.—Kingston Mineral, Ltd., Wales, has met environmental responsibilities at its four quarries producing crushed stone.[22] Dust suppression and collection was accomplished by enclosing conveyor systems and installing high-efficiency cyclones and air-treatment plants. Similar pollution control devices were installed at their new coated stone plants. Crushed limestone from the Batts Combe quarry of Amalgamated Roadstone Corp., Ltd. in Somerset will be shipped to the British Steel Corp. Llanwern Steelworks in Monmouthshire, England. Half of the limestone will be used for metallurgical purposes and the other half for making lime.[23]

Amalgamated Roadstone Corp., Ltd., continued exploitation of its granite deposit at Castle-An-Dinas in Cornwall. Increasing demand for crushed stone to satisfy local, national, and continental markets led the company a few years ago to install new crushing, screening, and coating plants at the quarry. Current plans called for modernizing its mobile equipment, and the acquisition of a fleet of eight-wheeled vehicles for external deliveries. The company maintains a ship-loading facility at Newlyn, which is serviced by a railroad line. In the belief that major export markets can be developed, the company has made a considerable effort to market its crushed granite in West Germany, the Netherlands and France.[24]

TECHNOLOGY

Rock fragmentation from bench blasting was studied by the Federal Bureau of Mines.[25] Eight test blasts were fired in a 2½ foot bench in a limestone formation in a test that was 5% to 10% of full scale and closely proportional to a full-scale bench blast. A study of the largest fragments in a complete screen analysis of each muck pile was used to evaluate the effects of type of pattern, timing of initation, and test location. With a constant burden and stemming, fewer large fragments were produced when the spacing was equal to the burden than with the spacing 1½ times the burden. Overall fragmentation was considerably better with the square pattern than with the rectangular pattern.

The Bureau of Mines also conducted studies of ultra-fine grinding of industrial minerals such as marble, pyrophyllite, talc, mica, and others using the Bureau-developed and patented attrition-grinding process.[26] In statistically designed experimental programs, tests were made to determine large effects of variables such as feed pulp density, grinding medium size, and quantity of electrical energy consumed during grinding. In general, the test results indicated that the best conditions for particle size reduction were approached when grinding with coarser fractions of the sand grinding media, the higher sand-to-mineral weight ratio, and the higher feed pulp density.

A specially designed and built crushing plant was used to supply two major specifications of rock for use in building a dam in California.[27] A 3-mile-long, overland conveyor system was being used in California to supply crushed limestone and shale to a cement mill.[28] A study of the various transportation methods available indicated that the overland conveyor system had the lowest projected operating cost, and the discounted cash flow of savings yielded by the overland system justified the additional incremental capital investment required.

[r] Revised. W Withheld to avoid disclosing individual company confidential data; included with "Undistributed" (excluding possessions).

[1] To avoid disclosing individual company data, certain State totals are incomplete; therefore, direct comparisons between output and value data for 1971 and 1972 cannot be made. The portion not included has been combined with "Undistributed." The class of stone omitted from such State totals is noted in the summary chapter of this volume.

[2] Data may not add to totals shown because of independent rounding.

r Revised. W Withheld to avoid disclosing individual company confidential data.

[1] Includes irregular shaped stone and rubble.

[2] Includes flagging and other unspecified rough stone.

[3] Less than ½ unit.

[4] Includes other uses not specified.

[5] Includes figures where symbol W appears to avoid disclosing individual company confidential data. 1972 data also include uses not specified.

[6] Data may not add to totals shown because of independent rounding.

[7] Data includes small amounts of monumental and other rough stone where symbol W appears.

[8] Includes monumental stone and uses not specified (1972 only)

[9] Data includes small amount of monumental stone (1971 only).

[10] Includes monumental stone (1972) and uses not specified.

[11] Data combined to avoid disclosing individual company confidential data; also includes flagging, monumental, rough construction, and uses not specified.

[12] 1971 data include dressed stone used for house stone veneer and construction.

[13] 1971 data include stone for curbing.

[14] Data include dressed stone used in 1972 for construction, monumental, and structural and sanitary purposes; also, figures where symbol W appears to avoid disclosing confidential data in sandstone, quartz, and quartzite.

[15] Includes small amount of slate used for house stone veneer.

[16] Includes slate used for electrical purposes and where symbol W appears for slate.

[17] Includes slate used for aquarium bottoms, building stone, fireplaces, and flooring.

[18] Produced by the following States in 1972, in order of value of output and with number of quarries: Hawaii (4), California (16), New Mexico (3), Maryland (4), Pennsylvania (3), Virginia (1), Oregon (2), and Washington (3).

[19] Includes sawed stone and house stone veneer.

[20] To avoid disclosing confidential data, figures indicated by symbol W are included in "Total" for "Other stone."

[21] Includes small amount of uses not specified.

[22] Data includes stone for paving blocks, structural and sanitary purposes (excluding slate), and uses not specified; slate used for aquarium bottoms, building stone, fireplaces, and flooring.

Table 5.—Granite (dimension stone) shipped or used by producers in the United States in 1972, by States

State	Active quarries	Quantity (short tons)	Value (thousands)
California	8	5,429	$829
Connecticut	3	2,769	W

[r] Revised. W Withheld to avoid disclosing individual company confidential data.

[1] Produced by the following States in 1972, in order of tonnage: South Carolina, Mississippi, Texas, Michigan, Virginia, Indiana, North Carolina, Minnesota, and Nevada.

[2] Includes marl used in agricultural limestone, agricultural marl, and other soil conditioners and nutrients, and minor amounts of filler; 1971 data also include stone used in poultry grit and mineral food.

[3] Data include small amount of fill.

[4] Data include stone used in dense-graded road-base stone, lime manufacture, and uses not specified.

[5] Data may not add to totals shown because of independent rounding.

[6] Includes agricultural limestone, agricultural marl and other soil conditioners, and poultry grit and mineral food.

[7] Includes stone used in manufactured fine aggregate, terrazzo, cement manufacture, mine dusting (1972), asphalt fill (1972), drain fields, roofing aggregate, chips and granules, waste material (1972), other filler (1971), uses not specified, and any data represented by the symbol W in granite.

[8] Includes stone used for abrasives and mine dusting.

[9] Data include stone used in acid neutralization, building products, paper manufacture, roofing aggregates, chips and granules, waste material (1972), uses not listed in smaller quantities, uses not specified, and any data represented by the symbol W in limestone and dolomite.

[10] Data combined to avoid disclosing confidential data includes surface treatment aggregate (1972).

[11] Includes a minor amount of stone used in roofing aggregates, chips and granules, and any data represented by the symbol W in marble.

[12] Data represent uses not specified.

[13] Includes ground sandstone, quartz and quartzite. Excludes stone used in the manufacture of industrial sand in 1972.

[14] Includes stone used for agricultural purposes, building products, fill, porcelain, pottery and tile, roofing aggregates, chips and granules, uses not listed in small quantities, uses not specified, and any data represented by symbol W in sandstone, quartz and quartzite.

[15] Includes stone used in surface treatment aggregate, and bituminous aggregate (1972).

[16] Includes stone used for agricultural purposes, lime manufacture (1971), asphalt filler (1971), other fillers (1971), uses not specified, and any data represented by the symbol W in shell.

[17] Data include stone used for terrazzo (1972), asphalt and other fillers, drain fields, roofing aggregates, chips and granules, uses not listed in smaller quantities, uses not specified, and any data represented by the symbol W in traprock.

[18] Includes stone used for agricultural purposes, cement manufacture, roofing aggregates, chips and granules, uses not listed in smaller quantities, uses not specified and data represented by the symbol W in other stone.

[19] Data includes stone used in roofing aggregates, chips, and granules, building products, flour (slate), uses not listed in smaller quantities, and uses not specified.

Table 9.—Number and production of crushed-stone quarries in the United States, by size of operation

Annual production (short tons)	1971			1972

Sulfur and Pyrites

By Roland W. Merwin[1]

There were significant improvements in conditions in the sulfur industry over those of 1971, with production, shipments, and apparent domestic consumption reaching alltime highs. This was a result of an upsurge in sulfur demand for fertilizer manufacturing and an improvement in export demand. However, the price position remained weak at the lowest level in more than 20 years. This was a result of a continuing worldwide oversupply situation. There were indications at yearend that there might be a moderate improvement in domestic prices in 1973.

Production of Frasch sulfur increased substantially over that of the previous year, and there was an even larger increase in the production of recovered elemental sulfur. There was only a small increase in the production of sulfur in other forms. Shipments of sulfur in all forms by domestic producers increased because of increases in domestic consumption and export demands and a decline in imports. Shipments exceeded production, with the deficit being met by withdrawals from Frasch producers' stocks. The total value of shipments of sulfur in all forms increased from $176.2 million in 1971 to $194.3 million in 1972. However, the average net shipment value f.o.b. mine or plant for Frasch and recovered elemental sulfur, which accounted for 91% of the total shipments of sulfur in all forms in 1972, declined from $17.47 per long ton in 1971 to $17.04 per long ton in 1972.

The United States improved its position as a net exporter of sulfur in all forms. Exports of sulfur were substantially greater than those in 1971 in the face of strong competition and low price levels. There was a decrease in imports of sulfur in all forms. Imports from Canada decreased moderately below those of 1971, mainly because of the phasing out of pyrites imports. Imports from Mexico decreased sharply because of the imposition of duties under the provisions of the Antidumping Act.

[1] Includes 2 thousand tons of sulfur contained in native sulfur ores.
[2] Measured by quantity sold, plus imports, minus exports.

DOMESTIC PRODUCTION

Native Sulfur.—Native sulfur accounted for 72% of the domestic production of sulfur in all forms. All of it was produced from Frasch mines in Texas and Louisiana. No sulfur ore production was reported during the year.

In 1972, 13 Frasch mines produced sulfur; one of these was closed during the year. The producers and mines in Louisiana were Freeport Minerals Co. at Garden Island Bay, Grand Isle, Grand Ecaille, and Lake Pelto; Jefferson Lake Sulphur Co. at Lake Hermitage (closed in March); and Texas Gulf, Inc., at Bully Camp. The producers and mines in Texas were Atlantic Richfield Co. at Fort Stockton; Duval Corp. at Pecos; Jefferson Lake Sulphur Co. at Long Point Dome; and Texas Gulf, Inc., at Boling Dome, Fannett Dome, Moss Bluff Dome, and Spindletop Dome.

Production of domestic Frasch sulfur increased in 1972, being 4% more than that of 1971 and only 2% lower than the all-time peak production in 1968. This was a reflection of a substantial increase in the demand for sulfur in both domestic and foreign markets.

There was a continuing tendency to concentrate production in the larger low-cost mines to counteract the adverse effects of low sulfur prices. During 1969, nine producers operated 21 mines. By yearend 1972, this was reduced to five producers operating 12 mines. Based on the normal production rates prior to closing, these nine closures (two in 1969, five in 1970, one in 1971, and one in 1972) represented an apparent reduction in production potential of slightly more than 1 million tons per year.

The 12 mines remaining in operation at the end of 1972 increased their production over that of 1969 by 1,013,000 tons, or 16%, and over that of 1971 by 369,000 tons, or 5%. Seven of the mines showed increases in production rates over those during 1971, and the other five registered decreases. The five largest mines, with production rates in excess of 1/2 million tons per year each, accounted for 73% of the total Frasch sulfur output for the year. Four medium-size mines, with production rates of more than 250,000 tons per year each, contributed an additional 19% of the year's production. The remaining 8% of the output came from four smaller mines, one of which closed during the year.

Ten mines, operated by the Duval Corp., Freeport Minerals Co., and Texas Gulf, Inc., accounted for most of the production. Only a relatively small portion of the output was obtained from the other two producers, operating three mines. By yearend, this was reduced to two companies with one mine each.

Producers' shipments of Frasch sulfur increased by 13% over those in 1971 as a result of improved demand for domestic consumption and export. The shipments exceed production by 323,000 tons, or 4%, with the shortage being met by withdrawals from producers' stocks. Approximately 76% of the shipments were for domestic consumption and 24% for export.

[r] Revised.
[1] Data may not add to totals shown because of independent rounding.
[2] F.o.b. mine.

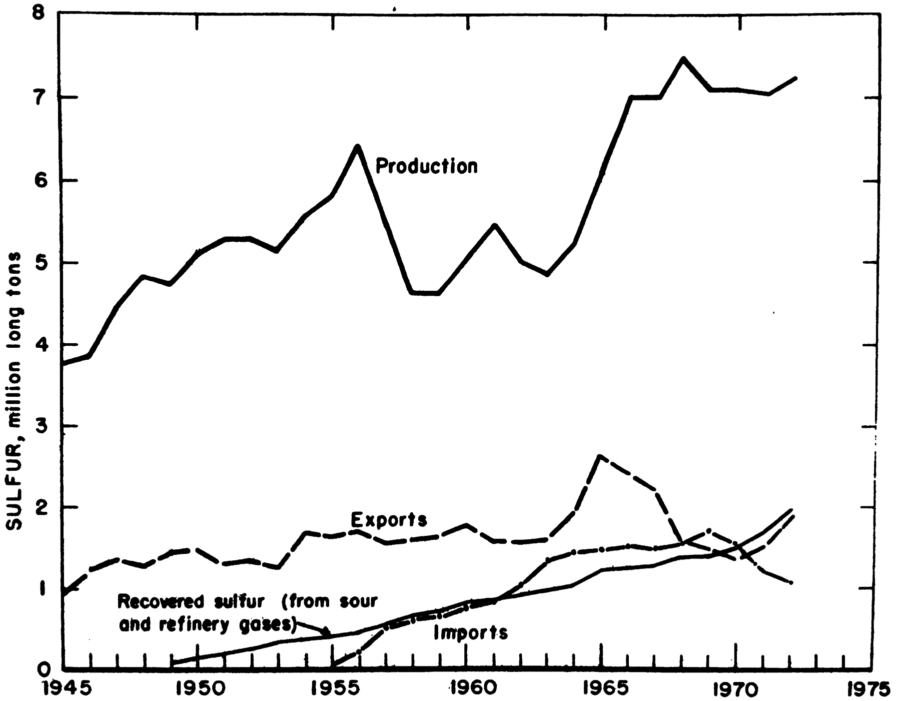

Figure 1.—Domestic Frasch and recovered sulfur production, imports for consumption and exports of native sulfur.

The total value of the shipments, f.o.b. mine, increased by 12%. However, the average reported unit shipment value, f.o.b. mine, was only $17.39 per ton compared with $17.50 per ton in 1971, reflecting a continued weakness in sulfur prices.

Recovered Sulfur.—Elemental recovered sulfur accounted for 19% of the total domestic production of sulfur in all forms. It was produced at 115 plants in 25 States. The 10 largest of these plants accounted for 39% of the total, and the combined production of the five leading States amounted to 74% of the total.

The production was nondiscretionary, as a byproduct from natural gas and petroleum refining operations. As such, it was produced and marketed regardless of demand or price and generally sold in close proximity to the points of production. Approximately 58% was produced at refineries or at satellite plants treating refinery gases, and 42% was produced at natural gas treatment plants.

Production and shipments of this product in 1972 reached alltime highs, with an increase of 21% and 20%, respectively, over those in 1971. However, the total value of the shipments increased by only 8% because of local competitive factors in domestic markets, including competition from Canadian sources in the northern areas of the Nation. The average reported shipment value, f.o.b. plant, was only $15.63 per ton as compared with $17.37 per ton in 1971, a decrease of 10%.

The five largest recovered sulfur producers were Amoco Production Co., Getty Oil Co., Gulf Oil Corp., Shell Oil Co., and Stauffer Chemical Co. Together, their 33 plants accounted for 49% of recovered sulfur production.

An important development during the year was the emergence of the States of Alabama, Florida, and Mississippi as potential major producers of recovered sulfur. This development was based on the rapidly expanding exploitation of dry sour natural gas and sour natural gas associated with petroleum in the deep Jurassic formations underlying these States. Shell Oil Co.'s Thomasville, Miss., recovered sulfur plant began operating in late July 1972 treating dry sour natural gas. It has a rated capacity of 1,250 tons of sulfur per day and is the largest plant of its kind in the United States. Additionally, several other companies began operating sulfur recovery plants in Alabama and Florida to treat sour natural gas associated with petroleum and condensate. There were plans for the installation of additional sulfur recovery plants in this three-State area with the expectation that recovered sulfur production in this region might increase to approximately 1 million tons per year within the next few years.

[1] Combined to avoid disclosing individual company confidential data; includes Alabama (1972), Delaware, Kansas, Missouri, Montana, North Dakota, Ohio, and Virginia.

[2] Data may not add to totals shown because of independent rounding.

Byproduct Sulfuric Acid.—The sulfur contained in byproduct sulfuric acid produced at copper, lead, and zinc roasters and smelters during 1972 amounted to 5% of the total domestic production of sulfur in all forms. It was produced at 15 plants in 11 States. Six acid plants operated in conjunction with copper smelters, and nine plants operated as accessories to lead and zinc roasting and smelting operations. The five largest acid plants accounted for 63% of the output, and the combined production of five States amounted to 84% of the total. The total output was 5% more than that in 1971, and the value of shipments was 8% more than that in 1971.

The five largest producers of byproduct sulfuric acid were American Smelting and Refining Co., The Bunker Hill Co., Kennecott Copper Corp., New Jersey Zinc Co., and St. Joe Minerals Corp. Together, their 10 plants produced 81% of the output during 1972.

Pyrites, Hydrogen Sulfide, and Sulfur Dioxide.—The contained sulfur in these products accounted for 4% of the total domestic production of sulfur in all forms during 1972. Pyrites was produced at three mines in three States; hydrogen sulfide at five plants in two States; and sulfur dioxide at one plant. Output was 2% less than that in 1971. The value of these combined products was 3% less than that in 1971.

The four largest producers of these products were Phillips Petroleum Co. (hydrogen sulfide), Shell Oil Co. (hydrogen sulfide), Standard Oil Co. of California (hydrogen sulfide), and Cities Service Co. (pyrites and sulfur dioxide). Together, the one mine and five plants accounted for 98% of the contained sulfur produced in the form of these products.

1972	283	149	432	9,227

CONSUMPTION

Apparent consumption of sulfur, in all forms, reached an alltime high in 1972. It was 7% more than that of 1971 and 6% more than the previous alltime peak consumption in 1967. This high level of consumption reflected an improvement in demand by the fertilizer industry. There were indications that this condition would continue to improve during 1973.

Sulfur for domestic consumption was obtained mainly from domestic sources: Frasch, 59%; recovered, 19%; and combined byproduct sulfuric acid, pyrites, hydrogen sulfide, and sulfur dioxide, 10%. The remaining 12% of the sulfur was obtained by substantial imports of Frasch and recovered sulfur and by minor imports of pyrites.

Domestic producers of elemental sulfur increased their apparent sales to domestic consumers: Frasch producers by 559,000 tons, or 11% over those in 1971; and recovered sulfur producers by 324,000 tons, or 20%. The reported sale or use of byproduct sulfuric acid, pyrites, hydrogen sulfide, and sulfur dioxide by domestic producers in the domestic market increased by 18,000 tons, or 2%. Imports of elemental sulfur and pyrites for domestic consumption decreased by 241,000 tons, or 17%.

Approximately 90% of the sulfur consumed was in the form of sulfuric acid. The manufacture of fertilizers accounted for approximately 53% of all sulfur consumption. Together, plastic and synthetic products, paper products, paints, nonferrous metals production, and explosives accounted for approximately 20% of demand. The remaining 27% was used for a large number of relatively small individual end uses.

The approximate distribution of consumption was as follows: Southern States, 67%; North Central States, 12%; Western States, 12%; and Northeastern States, 9%.

[2] Includes consumption of hydrogen sulfide and liquid sulfur dioxide.

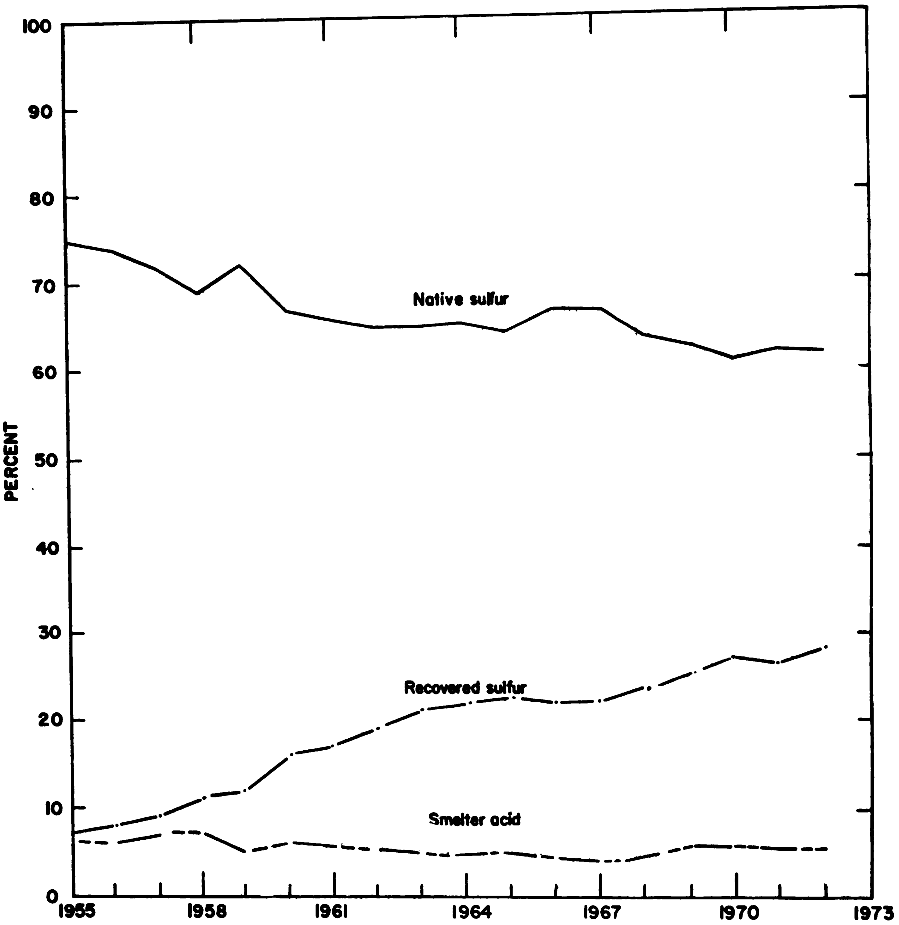

Figure 2.—Sulfur supply sources as a percent of total apparent consumption based on sulfur content.

STOCKS

Yearend producers' stocks of combined Frasch and recovered sulfur were 8% less than those at yearend 1971 because of withdrawals from Frasch stocks to meet a demand that exceeded production. This was the first reduction in producers' stocks since 1967. The combined yearend stocks amounted to approximately a 5-month supply, based on the 1972 domestic and export demands for domestically produced Frasch and recovered sulfur.

Table 10.—Producers' yearend stocks

(Thousand long tons)

Year	Frasch	Recovered	Total
1968	2,576	79	2,655
1969	3,243	95	3,338
1970	3,744	85	3,829
1971	4,023	97	4,120
1972	3,665	129	3,794

PRICES

Producers of Frasch and recovered elemental sulfur report the value of their shipments f.o.b. mine or plant. Such values vary widely between different mines or plants, depending upon prevailing selling prices in the markets they individually serve and the transportation costs to these markets.

The values f.o.b. mine or plant do not necessarily reflect the ultimate selling prices because most sales of elemental sulfur, generally in the form of molten sulfur, are made ex-terminal near the points of consumption. Due to the highly competitive nature of the transactions, prices are not generally made available. The trade journal, Sulphur, reported bimonthly on sales prices by areas on the basis of the best information available.

In general, prices remained relatively stable throughout the year in those major consuming areas served by the Frasch industry. However, prices weakened throughout the year in those consuming areas primarily served by producers of recovered sulfur.

Early in 1972, several major sulfur producers independently announced increases in the price of liquid sulfur ex-terminals, ranging upwards to about $3 per ton in the Tampa, Fla., area to be effective March 1, 1972, or as soon thereafter as contractual agreements permitted. Shortly thereafter, however, these increases were rescinded because of nonacceptance by major consumers under the terms of prevailing meet or release contracts. By the end of 1972, an increasingly strong demand for sulfur by fertilizer manufacturers had created a situation in which sulfur was in short supply in the major fertilizer manufacturing areas. It became evident that this situation, coupled with the increasing cost of producing Frasch sulfur, would lead to price increases in Tampa, Fla., and other fertilizer centers in early 1973.

FOREIGN TRADE

The United States improved its position as a net exporter of sulfur. Exports of sulfur in all forms in 1972 were 21% more than those in 1971, and imports in all forms were 17% less than those in 1971. In 1972, exports of elemental and processed sulfur exceeded imports of elemental sulfur and sulfur contained in pyrites by 664,000 long tons. In 1971, exports of sulfur in these forms exceeded imports by only 107,000 tons. The improvements in the export-import balance reflected strenuous efforts on the part of domestic producers to maintain their competitive position in both domestic and world markets in the face of strong foreign competition and low price levels. Favorable factors included the devaluation of the U.S. dollar, the imposition of countervailing duties on elemental sulfur imports from Mexico under provisions of the Antidumping Act, and logistic problems limiting sulfur exports from Canada to world markets other than the United States.

Exports were almost entirely in the form of elemental Frasch sulfur. The tonnage of elemental sulfur exported during 1972 was 21% greater than in 1971. However, the total value increased by only 16%, with the average reported value of $18.17 per ton in 1971 declining to $17.55 per ton in 1972. Together, Belgium and the Netherlands received 62% of these exports, mainly for transshipment to other European Economic Community (EEC) countries. Brazil, with 12%, was the third largest customer.

Imports of sulfur consisted largely of recovered sulfur from Canada and Frasch sulfur from Mexico. Imports from Canada in 1972 were 2% more than those in 1971. However, imports from Mexico were 40% less than those in 1971, primarily because of the imposition of antidumping duties. The total quantity of elemental sulfur imported was 12% less than that in 1971, and the total value decreased by 36%. The average declared customs value in 1972 was $14.32 per ton, whereas in 1971 the average was $19.57 per ton.

Estimated imports of pyrites from Canada in 1972 were 100,000 tons, containing 50,000 tons of sulfur, or only 38% of those in 1971. (Bureau of Census data do not include all shipments.) Imports of pyrites were phased out in 1972 because this product was no longer competitive with low-cost domestic elemental sulfur.

Acting under the provisions of the Antidumping Act, the U.S. Government completed an ongoing investigation of the sales of Mexican elemental sulfur within the United States and initiated a similar investigation relating to the importation of Canadian sulfur.

On February 3, 1972, the U.S. Department of the Treasury announced its determination that elemental sulfur from Mexico was being, or was likely to be, sold in the U.S. market at less than fair value within the meaning of the Antidumping Act.[2] On February 9, 1972, the U.S. Tariff Commission announced that having received this advice from the Department of the Treasury on sulfur imports from Mexico, it was instituting an investigation to determine whether an industry in the United States was being, or was likely to be, injured or prevented from being established by reason of these imports.[3]

The Tariff Commission on May 4, 1972, announced that it had unanimously determined that an industry in the United States was being injured by reason of the importation of elemental sulfur from Mexico at less than fair value.[4] On June 26, 1972, the Department of the Treasury announced that it was adding elemental sulfur from Mexico to the list of findings of dumping currently in effect.[5] This action made sulfur imports from Mexico subject to duties retroactive to the date of the prior Withholding of Appraisement notice on November 2, 1971.

On February 17, 1972, the Bureau of Customs, Department of the Treasury, announced that it had completed a summary investigation of information it had received that tended to indicate that elemental sulfur and nonelemental sulfur produced in Canada was being sold for exportation to the United States at less than the prices for home consumption or the cost of production. Therefore, the Bureau of Customs was initiating an inquiry to determine if there was a fact or likelihood that such sales were, or were likely to be, at less than fair value within the meaning of the Antidumping Act.[6] On April 13, 1972, the Bureau of Customs announced that its investigation of sulfur imports from Canada was being limited to elemental sulfur.[7]

On May 3, 1972, the Bureau of Customs, announced that it was undertaking a review of the extent to which price information relating to sales below cost of production might be used in determining fair value within the meaning of the Antidumping Act.[8] Although not so stated, it appeared that this review would relate to the ongoing investigation of sales of Canadian sulfur in the United States because the main basis of the complaint upon which the sulfur investigation was initiated was to the effect that sales of Canadian sulfur were being made at less than cost of production. The investigation of Canadian sulfur sales in the United States was continuing at yearend.

WORLD REVIEW

For the world as a whole, production of sulfur in all forms increased substantially over that of 1971. Similarly, there was an increase in sulfur demand, primarily because of an upsurge in the demand for use in the manufacture of fertilizers. However, continuing the pattern prevalent during the past several years, production exceeded demand. As a result, there was an increase in producers' stocks, particularly in the case of Canadian recovered sulfur. Prices remained relatively stable compared with those of 1971, but at levels that were so low as to create serious problems for sulfur producers. The low-price situation was of particular concern to the producers of Frasch sulfur because, as compared with secondary producers, they had no coproduct income available to meet rising production costs. The worldwide oversupply situation was tempered by logistic problems that restricted the movement of sulfur from certain major producing areas, such as Canada, to world markets. As a result, there was more of an effective equilibrium between consumption and available supply than the overall statistics would suggest.

There was a continuation in the trend toward basic restructuring of world sulfur supply sources with increasingly larger supplies being obtained from secondary sources such as sour natural gas and environmental-related sulfur recovery processes. Production of primary elemental sulfur from Frasch and sulfur ore mines remained relatively steady. The pyrites sector of the industry continued to face serious problems as this commodity was becoming increasingly noncompetitive with sulfur from secondary sources.

Canada.—The Province of Alberta's production of recovered elemental sulfur increased from 4.5 million long tons in 1971 to 6.5 million tons in 1972 as a result of the completion of several new plants and the expansion of production at other plants. The production was nondiscretionary, being produced at sour natural gas treatment plants, and was spurred on by an increasingly heavy demand for natural gas in U.S. markets. Shipments of sulfur increased only slightly, from 2.7 million tons in 1971 to 3.1 million tons in 1972. As a result, producers' yearend stocks increased from 5.3 million tons in 1971 to 8.7 million tons in 1972. The value of the marketed sulfur, f.o.b. plant, decreased from approximately $7.22 per ton in 1971 to $5.71 per ton in 1972.[9]

With no new major sulfur recovery plant construction currently underway, it was estimated that Alberta's recovered sulfur production in 1973 would level off at approximately 7 million tons per year. Canada's National Resource Council estimated that unless substantial new markets were developed, producers' stocks of sulfur in Alberta might reach 40 million tons by 1980.[10] In addition to the problem of oversupply, Alberta's producers were faced with the problem of meeting sulfur emission standards at their plants. It was estimated that the cost of complying with environmental standards would be approximately $34 million.[11]

Cyprus.—The mining industry of Cyprus was severely affected by the weakness in international pyrites trade and strong competition from other countries in the European market. Both production and exports have been dropping steadily during the last few years, and producers' stocks have increased. It appeared that the only solution to the problem would be the establishment of a domestic fertilizer industry.[12]

France.—Société Nationale des Pètroles d'Aquitaine (SNPA) strengthened its position in the international sulfur trade when it commissioned a second liquid sulfur tanker. SNPA, owned jointly by the government and private interests, has long been the Nation's leading recovered sulfur producer and a major supplier of sulfur in the European markets.[13]

India.—As a major sulfur importing country with limited domestic sources and a rapidly growing demand, India has been making strenuous efforts to increase its production of this commodity. These efforts have been along the lines of increasing pyrites production, the recovery of sulfur from petroleum refining operations, and the production of byproduct sulfuric acid from metallurgical operations. However, there have been continuing delays in the implementation of these programs. Given further delays, significant increases in sulfur imports were forecast to 1980.[14]

[13] Sulphur (London). Aquitaine's New Liquid Sulphur Tanker. No. 101, July–August 1972, pp. 20–22.

Iraq.—Production of Frasch sulfur at the Mishraq mine of the Iraq National Minerals Co. was officially inaugurated in January 1972. The planned initial operating rate was 250,000 tons per year with the intention of increasing the output to 1 million tons per year by the end of 1972.[15]

Italy.—Typical of the problems facing nations with high-cost sulfur mines is the situation that Sicily's Regional Minerals Agency, Ente Minerario Siciliano (EMS), has encountered in its efforts to phase out Sicily's sulfur mines. These mines were major world sources of sulfur at one time but are no longer economical. Proposals to close the remaining mines have been strongly opposed by political and labor organizations. Despite these repeated efforts, EMS was still operating seven mines employing 3,569 workers. Deficits at these operations have been running between $4 and $5 million per year and now total slightly over $30 million.[16]

Japan.—The Japanese Ministry of International Trade and Industry (MITI) published its estimates of Japanese elemental sulfur supply and demand through 1976. In the past, Japanese supply and demand for sulfur in all forms have been very nearly equal. However, the analysis indicated a very rapid growth in recovered sulfur output, primarily from petroleum desulfurization plants to meet antipollution requirements. It was predicted that by 1976 production of recovered elemental sulfur from these sources would exceed domestic demand by approximately 525,000 tons and would place Japan in the position of becoming a major exporter of sulfur.[17] Another independent analysis of Japanese sulfur supply and demand was in general agreement with the predictions of MITI. This study suggested that in 1980 the production of elemental sulfur at refineries would exceed domestic demand by 1.2 million tons per year.[18]

Mexico.—The export-oriented Frasch sulfur industry was adversely affected by the imposition of antidumping duties on the importation of Mexican sulfur into the United States as, historically, the U.S. market had been Mexico's major customer. As a result of this action, reported imports of Mexican Frasch sulfur into the United States during 1972 were only 60% of those in 1971. Strong efforts were made to develop new markets, with arrangements being made for initial shipments to the People's Republic of China and Chile.[19]

Netherlands Antilles.—The Lago Oil and Transport Co. placed a residual oil desulfurization unit onstream in late 1971. The plant, built at a cost of approximately $35 million, had a rated capacity of 100,000 tons of recovered elemental sulfur per year. Plans were announced for the construction of a second desulfurization plant at a cost of approximately $110 million, with completion scheduled in 1974.[20] These actions were indicative of the projected future expansion of recovered sulfur production from sour crudes in the Caribbean area.

Spain.—Plans were announced for a new oil refinery complex at Tarragona. Feedstocks of the refinery would be low-gravity, high-sulfur crude oil from an offshore field in an area belonging to Spain. Plans for the refinery included a desulfurization unit that would produce 44,000 tons of sulfur per year.[21] The pyrites mining industry, the mainstay of Spain's sulfur industry, was confronted with a decrease in demand for this product in its established foreign markets. Plans were made to improve this situation by the establishment of fertilizer manufacturing industries in Spain utilizing pyrites as a source of sulfuric acid.

U.S.S.R.—Although there was still heavy dependence on pyrites as a source of sulfur, the U.S.S.R. began to emphasize the production of native sulfur ores, Frasch sulfur, recovered sulfur from sour natural gases, and byproduct sulfuric acid from metallurgical operations. In 1972 the principal producing centers of native sulfur continued to be Rozdol and Yavorov (West Ukraine); Gaurdak, Shorsu, and Changyrtash (central Asia); and Alekseyev and Vodninsk in the Kuybyshev sulfur complex (Volga group). The Rozdol complex is the major producer of native sulfur and, with the Gaurdak combine, provided the bulk of the country's sulfur requirements. A Frasch mine was placed in operation at the Gaurdak combine in 1972. A contract was awarded for the construction of a major recovered sulfur plant at Orenburg. J. F. Pritchard & Co. and a French affiliate, Cie. Centrale d'Etudes Industrielles, will provide equipment and management services for the $76 million plant, which will handle 1,600 million cubic feet of sour natural gas per day and produce over 2,000 tons of sulfur per day.

Grand total	[r] 22,162	22,722	25,795

[e] Estimate. [p] Preliminary. [r] Revised.

[1] In addition to countries listed, Uruguay produces less than 500 tons of sulfur annually as a byproduct of petroleum refining.

[2] Year beginning March 21 of year stated.

[3] Includes small quantity of byproduct sulfur recovered from sulfide ores as well as sulfur content of sulfur ores.

[4] From petroleum refining.

[5] Includes in part sulfur content of H_2S converted directly into sulfuric acid.

[6] From processing of natural gas, petroleum, tar sands, and sulfide ores.

[7] From petroleum refining and smelting of sulfide ores.

[8] From petroleum refining and natural gas processing.

[9] From petroleum refineries only. Excludes an unreported quantity recovered from sulfide ores, which is included above (see footnote 3).

[10] From distillation of petroleum and lignite and from reduction of SO_2 gas.

[11] Includes sulfur recovered from petroleum refineries and from other unspecified sources.

[3] Less than one-half unit.

TECHNOLOGY

Technological developments during 1972 were largely related to the recovery or abatement of environmental-related sulfur. Fundamentally, this was brought about by the necessity for the removal of sulfur from solid, liquid, and gaseous effluents, or wastes for the protection of the environment. Additionally, research efforts were devoted to the development of new uses for sulfur because the present and projected supplies of sulfur from secondary sources promised an overwhelming oversupply.

The Bureau of Mines reported on the chemistry of sulfur dioxide as related to methods for removing it from waste gases. The chemistry of current or potential sulfur dioxide (SO_2) removal processes was classified into four groups: (1) Reduction, (2) liquefaction, (3) direct dissolution, and (4) oxidation. Methods that involved reducing SO_2 to elemental sulfur appeared promising. Thermodynamic data were presented as guidelines to postulate which reactions were most likely to occur.[22]

The Bureau of Mines reported that prolonged laboratory and limited pilot plant tests have shown that the Bureau's citrate process is capable of removing 95% to 99% of the SO_2 from industrial waste gases with essentially all of the SO_2 being converted to elemental sulfur. The chemistry and mechanism of the process were described, initial laboratory and pilot plant data were summarized, and second-generation laboratory operation and pilot plant design were reviewed. Preliminary cost estimates were presented for recovering sulfur from copper smelter gas, powerplant flue gas, and Claus plant tail gas.[23]

Ammonia injection followed by gas cooling was demonstrated as an effective means for removing SO_2 from the gas phase in combustion gas mixtures. Product sulfur-bearing salts, which are entrained in the gas, could be removed in a single-stage water scrubber, and ammonia could be effectively regenerated from the scrubber liquid through reaction with sodium hydroxide solutions.[24]

The Bureau of Mines reported that several advancements had been made in a novel process being developed for converting coal into clean fuel oil that has very low sulfur and ash contents. Coal conveyed in recycle oil was propelled by rapid turbulent flow of hydrogen through a reactor packed with immobilized (fixed-bed) catalyst pellets. A relatively low-value, high-sulfur coal having 4.6% sulfur and 17% ash was continuously converted in a small pilot plant into high-value fuel oil having only 0.19% sulfur and 1% ash.[25]

The Office of Coal Research, U.S. Department of the Interior, conducted research programs on methods of converting the Nation's massive coal reserves into required clean fuel forms, and developing more efficient, clean ways of producing electric power from high-sulfur coal. Most of the proposed processes would produce elemental sulfur as a byproduct.[26]

The Bureau of Mines reported on the status of the Synthane process for converting coal to a gas having the essential characteristics of natural gas, with the recovery of sulfur as a byproduct. The report described some of the early experimental work on coal pretreatment and gasification, gas purification, and methanation from which the Synthane process evolved. Also discussed were current plans for pilot plant scale-up of the process.[27]

A review was made of 30 processes for the recovery of sulfur from metallurgical flue gases. The processes were listed and analyzed by process name, sponsor, reducing or absorbing agent, end product, process description, analysis of the process, and stage of development.[28]

The design and operation of a pilot plant for the production of elemental sulfur from smelter stack gases was described.

The process uses reformed natural gas to reduce sulfur dioxide to elemental sulfur. The capital and operating costs of a commercial installation were estimated.[29]

The status of several new processes for the desulfurizing of residuum fuel oils was reviewed. Residuum desulfurization was experiencing rapid technological progress, chiefly in the area of catalyst improvement. However, commercial development has been limited to a small number of full-scale plants mainly because of economic considerations. Still unanswered was the relative economics of residuum desulfurization compared with the cost of powerplant stack cleanups.[30]

A new refinery tail gas desulfurization process was described that utilized a dry, regenerable absorbent based on copper oxide. It was stated that the advantages of such a dry acceptor material were (1) no loss of thermal buoyancy in the gas and (2) no waste-disposal problem. There were plans to install a commercial unit in a refinery in Japan.[31]

Past, present, and future sulfur sources and uses were reviewed. It was concluded that a rapid increase in sulfur production in the next few years seems inevitable, and that large-scale new uses would be required to avert a depressing surplus situation. Although it appeared that many potential new uses for sulfur existed, it would be necessary to engage in serious research development work to bring such applications to fruition.[32]

The necessity of developing new uses for sulfur was analyzed. The preliminary efforts being made in the United States and Canada to develop new sulfur uses were reviewed, as were several prospective new uses toward which research could be devoted.[33]

The Canadian program for the development of new uses for sulfur was reviewed. The program would be conducted under the auspices of the Sulphur Development Institute of Canada (SUDIC). Financing in the amount of $1 million per year for 3 years would be provided by the Federal Government of Canada, the Provincial Government of Alberta, and industry organizations.[34]

The Bureau of Mines initiated a research program with the objective of developing new high-tonnage uses for sulfur and sulfur compounds. The initial phases of the program consisted of elements pertaining to development of new major uses, testing to establish physical chemical properties of materials made from sulfur, and the systematic collection of basic knowledge that would contribute to identifying new novel consumption potentials. Potential applications that were being investigated included sulfur-asphalt paving materials, sulfur applications for land pollution abatement, characterization of construction materials containing sulfur, and new metallurgical applications for sulfuric acid.[35]

Talc, Soapstone, and Pyrophyllite

By J. Robert Wells [1]

Total U.S. production of talc, soapstone, and pyrophyllite (known collectively as the talc-group minerals) was greater in 1972 than in any previous year, almost half again as much as a decade ago in regard to both tonnage and total value.

American Talc Co., Inc., previously operating only in Alabama, extended its talc mining to Montana with the acquisition in 1972 of the Willow Creek mine in Madison County. Johns-Manville Corp. (headquarters now in Denver, Colo.) acquired the California properties of L. Grantham Corp. at midyear. Grantham, operating the Warm Springs mine and grinding facilities in the southwestern part of Death Valley, Inyo County, was for many years one of the largest producers of high-quality talc in the United States.

Talcum powder, the familiar and best known form in which talc is used, was unjustly stigmatized in the August 1972 deaths of a number of infants in France. After investigation, it was determined that the tragedy was the result of an excessive quantity of a bactericide that had been added to the powder.

Some industrial talc producers and users were experiencing an increasingly difficult situation in 1972 because of the close mineralogical relationship between talc and a group of other minerals, some of which may become carcinogenic under conditions involving long-continued inhalation. No authoritative distinction has ever been drawn between talc and tremolite, a substantial proportion of which is known to be present in some grades of fibrous talc. That ambiguity and a tendency to regard tremolite as a form of asbestos, in combination with growing emphasis on environmental and health considerations, began to plant doubts concerning industrial talc's hitherto unquestioned classification as an essentially harmless and unrestrictedly usable raw material.

Legislation and Government Programs.—The Defense Materials Inventories prepared by General Services Administration (GSA) showed that Government holdings as of December 31, 1972, included 1,180 short tons of talc (steatite, block or lump), with a market value of $383,500, and 3,900 short tons of talc (steatite, ground) valued at $21,400. Of the block or lump steatite, 980 short tons was listed as excess inventory, as was also the entire quantity of ground material. During calendar 1972, 24 tons of block material, valued at $7,800, was sold from stockpile inventory, but none of the ground talc was disposed of.

---

[1] Physical scientist, Division of Nonmetallic Minerals.

In June 1972 the Occupational Safety and Health Administration (OSHA) published regulations governing the size and number of fibers of asbestiform minerals (genetically related to talc and often accompanying it in its ores) that may enter the atmosphere at mineral processing plants. Some restraint on industrial utilization of talc, especially of the tremolitic type, was foreseen as a consequence of these controls. The Food and Drug Administration (FDA) set forth a proposal calling for complete elimination of asbestos particles from talc used in the preparation or packaging of all foods and/or cosmetic and drug products. No suggestion was offered concerning sampling and analytical procedures capable of establishing the complete absence of such particles.

DOMESTIC PRODUCTION

The total tonnage of U.S. mine production of talc-group minerals in 1972 was 7% greater than the previous high mark set in 1971, and the corresponding total value was nearly 1% above the then alltime high reached in 1970.

Talc-group minerals were produced in the United States from a total of 54 mines distributed throughout Alabama, Arkansas, California, Georgia, Maryland, Montana, Nevada, New York, North Carolina, Oregon, Texas, Vermont, Virginia, and Washington. Talc or soapstone was mined at one or more locations (48 in all) in each of those 14 States. Domestic production of pyrophyllite consisted, for the first time in more than 20 years, of the output of just one State, North Carolina, where six mines supplied that mineral.

Five States, led by New York and with Texas, Vermont, California, and Montana following in descending order, provided 86% of the total 1972 talc-group tonnage; the same States, in nearly the same order except with Vermont nosing out Texas for second place, also made up 86% of the corresponding total value. The largest domestic producers of talc-group minerals in 1972, accounting jointly for three-quarters of the total tonnage and two-thirds of the total value, were (in alphabetical order) Cyprus Mines Corp., United Sierra Division, with operations in California, Montana, and Texas; Eastern Magnesia Talc Co. in Vermont; L. Grantham Corp. in California; International Talc Co., Inc., in New York; Pfizer Inc., Minerals, Pigments & Metals Division, in California and Montana; Southern Clay Products, Inc., in Texas; R. T. Vanderbilt Co., Inc., with subsidiaries Gouverneur Talc Co., Inc., in New York and Western Talc Co., Inc., in California; and Windsor Minerals, Inc., in Vermont.

Talc minerals were ground for sale or industrial use in 1972 at approximately 40 mills operated by 30 companies in 12 States. Talc or soapstone mined in Arkansas, Nevada and Washington was ground elsewhere, while talc that originated in another State was ground in Nebraska, where there was no mine production.

1972	89,949	521	994,263	33,188	1,084,212	33,709

[1] Data may not add to totals shown because of independent rounding.

CONSUMPTION AND USES

Apparent consumption of talc-group minerals in the United States in 1972 (total sales plus imports minus exports) amounted to 942,000 short tons (compared with 860,000 tons in 1971 and 873,000 tons in 1970), setting a new high mark for this figure, almost 1% above the previous record established in 1969.

Reported sales of ground material totaled 17% more in tonnage than in 1971, and the total value was 27% higher, with especially large gains in tonnage being scored by California, New York, and Texas and in value by California, Georgia, New York, North Carolina, and Texas.

Thirty percent of the total quantity of talc, soapstone, and pyrophyllite sold or used by domestic producers in 1972 was consumed in the manufacture of ceramics and 16% in paints. A salient feature of the 1972 end-use distribution of these materials was the marked difference in the proportion allocated to toilet preparations (12%, compared with 3% in 1971 and 2% in 1970), a divergence that is thought to be more a reflection of anomolous reporting in previous years than an indication of an abrupt upsurge in this utilization. The shares of the 1972 total that were taken by the other major consumption categories (insecticides, paper, roofing, and rubber products) were no more than fractionally different from the respective 1971 figures.

Table 4.—Pyrophyllite[1] produced and sold by producers in the United States

STOCKS

It was estimated, on the basis of a comparison of the figures reported in 1972 for domestic production of talc-group minerals and for the quantity of those materials sold or used, that U.S. producers may have had 167,000 short tons of mined talc, soapstone, and pyrophyllite on hand (crude, ground, or in process) on December 31, 1972, compared with 144,000 tons on that date in 1971 and 205,000 tons in 1970.

PRICES

The average of unit values reported by domestic producers of crude talc, soapstone, and pyrophyllite in 1972 was $7.08 per short ton, compared with $7.36 in 1971 and $7.56 in 1970. In contrast to that decline, the average unit value reported for all talc-group minerals sold or used by domestic producers (mostly processed material but not including finished cosmetic preparations) increased sharply to $31.09 per ton, compared with $27.51 in 1971 and $27.42 in 1970.

Engineering and Mining Journal, December 1972, quoted prices for domestic ground talc in carload lots, f.o.b. mine or mill, containers included, per short ton, as follows:

Vermont:	
98% through 325 mesh, bulk	$20.00
99.99% through 325 mesh, bags:	
Dry processed	55.00
Water beneficiated	81.00
New York:	
96% through 200 mesh	28.00
99.9% through 325 mesh	44.50
100% through 325 mesh, fluid energy ground	80.00–90.00
California:	
Standard	37.00– 53.00
Fractionated	37.00– 71.00
Micronized	62.00–104.00
Cosmetic/steatite	44.00– 65.00
Georgia:	
98% through 200 mesh	14.00
99% through 325 mesh	25.00
100% through 325 mesh, fluid energy ground	75.00

The price range quoted in Chemical Marketing Reporter, December 25, 1972, for carload lots of imported Canadian talc, ground, in bags, was from $20 to $35 per ton, f.o.b. works.

American Paint Journal, November 27, 1972, listed the following prices per ton for paint-grade talcs in carload lots:

California: 325 mesh, bags, mill:	
Fibrous, white, high oil absorption	$34.00–$37.00
Semifibrous, medium oil absorption	32.00– 73.95
Montana:	
Ultrafine grind, f.o.b. mill	70.00
New York: Fibrous and semifibrous, bags, mill:	
98% through 325 mesh	31.00
99.4% through 325 mesh	40.00
Trace retained on 325 mesh	80.00
Fine micron talcs (origin not specified)	68.00–111.50

FOREIGN TRADE

Exports.—The United States exported a greater quantity of talc-group materials in 1972 than in any previous year, topping the former record for tonnage (1971) by 26% and for value (1970) by 1%. The exported material went to a total of 57 countries, 18 in the Western Hemisphere, 17 in Asia/Oceania, 16 in Europe, and six in Africa. Sharply increased shipments to two major recipients, Canada and Mexico (up 54% and 25%, respectively, from 1971 figures), were the most notable factors contributing to the new record total.

Imports.—In 1972 the total value of U.S. imports of talc minerals for consumption reached the highest level on record, 29% above the mark set in 1970, and the 1972 tonnage was exceeded only by that of 1970, (3% higher). Outstandingly in first place among 1972 talc imports were receipts from Italy which added up to the largest tonnage from there since 1963 and to the highest total value ever recorded from any one country in any one year.

Tariffs.—Schedules applicable throughout 1972 provided for import duties on the various classifications of talc as follows: Crude and not ground, 0.02 cent per pound; ground, washed, powdered, or pulverized, 6% ad valorem; cut or sawed, or in blanks, crayons, cubes, disks, or other forms, 0.2 cent per pound; and other, not specially provided for, 12% ad valorem.

[1] Does not include talc, n.s.p.f.: 1970, $5,651; 1971, $17,997; 1972, $128,925.

[2] Less than ½ unit.

WORLD REVIEW

A private firm of marketing consultants, C. H. Kline & Co., of Fairfield, N.J., scheduled for completion in late 1972 two new surveys of the current and projected marketing situation, both domestic and international, of a number of filler and extender pigments, among which talc is a prominent example. The announced objective of the first study was a review of new developments and future trends in the U.S. market for those commodities; that of the second was an analysis of the factors and sometimes complex interrelationships affecting that market in parts of Europe, specifically Spain and the countries of the European Economic Community and the European Free Trade Association.

Australia.—Talc reserves at the Seabrook deposit near Meekatharra, West Australia, property of Westside Minerals, N.L., were estimated at 1 to 2 million tons of 76% ore easily extractable by selective open pit methods. Preparations were made to begin mining at an initial rate of 100,000 tons per year, and plans were revealed to process the output in a milling plant to be constructed especially for that purpose at the Indian Ocean port of Perth. Australia's total annual production of talc has ranged in recent years from less than 20,000 tons to over 140,000 tons.

Brazil.—Although no official quantitative data are published, Brazil has a substantial yearly output of talc and soapstone, mostly from Paraná and Minas Gerais, while lesser quantities are mined in Rio de Janeiro, São Paulo, and Bahia. There is a significant export trade in talc, and a growing cottage industry utilizes important quantities of soapstone in the production of hand-carved art objects.

Canada.—Three companies produce talc in Canada, one in Ontario and two in Quebec. The leader, Baker Talc Ltd., with properties near South Bolton, Quebec, has developed beneficiation procedures for upgrading its talc product to paint and paper grade; that process, involving both froth flotation and high-intensity wet magnetic separation, was placed in limited-scale operation in 1970 and went to full-scale in 1972.

Pyrophyllite was found to make up the bulk of an intrusive body of relatively recent geological age at the west end of the working pit of the newly developed Island

Copper Mine on Vancouver Island, British Columbia. Plans for commercializing the discovery were not mentioned.[2]

China, People's Republic of.—Talc-group minerals are among China's more important export items, and as much as half the yearly output of high-quality material from the Ta–ling deposit at Liaoning, southern Manchuria, may be sold overseas. Japan received about two-thirds of the approximately 80,000 tons exported in 1970, and lesser quantities went to destinations in Poland, the United Kingdom, and the U.S.S.R.

Egypt, Arab Republic of.—The most important sources of talc in Egypt are the Darhib and El Atshan mines in the Eastern Desert, the region bordering on the Gulf of Suez and the Red Sea. Large-scale production of ceramic- and pharmaceutical-grade talc from that area was curtailed in 1968 because of a heavy accumulation of stocks in the preceding years.

France.—An apparent outbreak of encephalitis in northern France that was accompanied by symptoms of acute skin irritation and which affected only small infants, resulted in at least 20 deaths. The illness was traced to the use in each case of one particular brand of baby powder, and statements were made that the fatalities had been caused by talcum powder. The French government's investigation showed that the tragic episode was attributable, rather, to an error in the formulation of the product. The preparation had been allowed to go on sale containing a lethal concentration (as high as 6%) of an effective but dangerous antibacterial agent, hexachlorophene.

Germany, West.—Talc imports in 1971 amounted to 10,300 short tons, 4% less than in the previous year. Austria was the principal source of the 1971 imports with 39% of the total (up from 36% in 1970). Other major suppliers in 1971 were Italy with 17%, France with 13% and Norway with 11%. The United States furnished 3% of West Germany's imported talc in 1970 but only a fraction over 1% in 1971.

India.—Recent mineral discoveries in northwest and north-central Kashmir State included talc deposits in the districts of Gilgit and Baltistan. Prospecting licenses were being granted seekers of talc and other specified minerals in that region with the understanding that such licenses will be convertible to 20- or 30-year mining leases in the event of successful exploration.

Italy.—Italian exports of talc-group minerals in 1971 amounted to nearly one-third of the total quantity produced, only fractionally different from the previous year's proportion. Among the principal recipients of the material exported in 1971 were West Germany, the United Kingdom, and the United States.

Korea, Republic of.—The government-controlled Korea Mining Promotion Corporation announced that a $4.8 million loan from the Asian Development Bank was being negotiated for the procurement of new mining equipment. The stated objective of this procurement and related modernization activities was the establishment of a situation to encourage production and use of an extensive list of domestic mineral raw materials. Among the products mentioned, talc and pyrophyllite (from the Tongyang and Sungsan mines, respectively) are rapidly attaining major importance as earners of foreign exchange.

South Africa, Republic of.—Figures for 1972 mineral production included 9,656 short tons of talc and 2,270 short tons of "wonderstone," the name given to a special variety of pyrophyllite that is mined locally. Exports accounted for only 2% of the tonnage of talc and 12% of the pyrophyllite, but the unit values of the exported materials (equivalent respectively to $51.00 per short ton and $213.00 per short ton) were indicative of the exceptional grades involved.

Swaziland.—A group of Japanese companies, headed by a Mitsubishi subsidiary, held discussions with Swaziland Industries (Pty), Ltd., with a view to initiating exploitation of a newly discovered deposit of pyrophyllite in the southwestern Highveld area, presumably to supply material for shipment to Japan. Swaziland Industries currently mines pyrophyllite from a deposit near Sicunusa in the Manzini district, but the entire output of that operation is exported to the Republic of South Africa.

Sweden.—Production of talc and soapstone in Sweden has averaged about 30,000 short tons annually throughout the last decade, but consumption of those materials has consistently exceeded the domestic output, and imports (chiefly from Austria and Norway) have substantially outweighed exports. In 1972 Sweden's mines yielded 26,450 tons of talc-group minerals, and 24,000 tons was imported at a total cost of $1.5 million. Only 1,800 tons, valued at $38,000, was exported.

[e] Estimate. [p] Preliminary. [r] Revised.

[1] In addition to the countries listed, Southern Rhodesia is believed to produce talc, but available information is inadequate to make estimates of output levels.

[2] Revised to zero.

[3] Includes talc and wonderstone (pyrophyllite).

[4] Less than ½ unit.

[5] Includes talc and pyrophyllite; in addition, pyrophyllite clay is produced as follows in short tons: 1970—507,112; 1971—854,160; 1972—843,180.

TECHNOLOGY

In an annual review of materials used for ceramic processing, an industrial journal presented informative summaries on the nature, occurrence, and applications of a number of talc-group minerals and related materials.[3] Research was successfully concluded in an effort to develop an advantageous method for beneficiating western talc ores in which the mineral is present in the soft, platy form. The procedure finally selected was characterized as an attrition-scrubbing sedimentation process.[4] The research program of the Bureau of Mines included experiments to evaluate the possible use of talc, glass fiber, and dicyclopentadiene in a sulfur matrix for building purposes. No expedient was discovered for combating destructive changes found to take place in the composites upon aging, and the outlook was considered to be unfavorable.

The raw materials (including talc and pyrophyllite), as well as the technologically advanced methods and equipment recommended for efficiently fabricating them into ceramic tile were discussed in a journal article,[5] and another article reviewed operations of a specific installation where those materials and techniques similar to those advocated are being employed.[6] Some of the technologic considerations involved in the utilization of a particular type of talc in a specified application were the subject of an article.[7] A detailed description of the emission-abatement program at facilities of a major talc producer was presented at a professional society meeting and was made available in booklet form.[8]

Particles of platy talc ore of cosmetic grade are effectually delaminated in a patented procedure by being subjected to a variety of selective forces that achieve maximum reduction in the thickness of the particles while leaving their lengths and widths relatively unchanged. The resulting low-density, high-slip product is described as lustrous and possessing optimum texture and lubricity so as to be exceptionally suitable for use in body powders.[9] Talc and graphite were specified to serve as thickeners for mixing with finely divided polytetrafluoroethylene and colloidal chrysotile asbestos to be combined with a major proportion of a lubricating oil in a patented formulation for a high-pressure lubricating grease.[10] A patent was issued for an improved printing ink, composed of ground talc, a pigment, and polyamide epichlorohydrin dispersed in a solvent.[11]

A process and equipment were patented for accelerating granules of talc, or other mineral substances, through a nozzle to supersonic velocities in order to pulverize the material by the standing shock wave so produced.[12] Finely divided talc, either micaceous or granular and amounting to as much as 50% of the total weight, can be added to a specified organic material to produce a patented substrate that will receive a metal surface suitable for electroplating.[13] A process was patented for reacting talc, lithium carbonate, sodium carbonate, and aqueous sodium silicate to produce a substance that can be dried for use in catalytic applications normally served by certain naturally occurring materials of the montmorillonite clays group.[14]

A patent was granted for a process in which talc, clay, feldspar, wollastonite, or other ceramic materials are combined in an aqueous mixture with an approximately equal quantity of exfoliated vermiculite, and that mixture is pressed into shapes that are then dried, fired, and glazed to produce strong and lightweight disposable containers.[15] In a process for which a patent was granted, an aqueous dispersion of pyrophyllite is applied to one surface of a paper form, after which the object is dried, coated with a glazing material, and fired to vitrify the glaze and consume the combustible base, thus producing inexpensive, thin-walled ceramic ware to be discarded after a single use.[16]

Thorium

By Roman V. Sondermayer [1]

As in the past, there was no direct mine production for thorium as such during 1972, and demand for thorium was not the decisive factor in determining its supply. Production of thorium was essentially a byproduct of the monazite operations for rare earths. Consequently, there was a continuing and excessive stock of thorium-bearing raw materials. The weak market continued, but the long-term potential for use of thorium was considered good. Demand for thorium hardener, used in magnesium alloys for aerospace applications, increased slightly. New orders for thorium-uranium-fueled high-temperature, gas-cooled reactors (HTGR) improved the long-range demand potential for thorium nuclear fuels. Continuing research may introduce new industrial applications for thorium and its compounds in metallurgy and nuclear fuels, thus resulting in larger consumption of thorium.

The most significant events related to thorium during 1972 were the beginning of a new beach-sand (containing monazite) operation in Florida, the preliminary accord for the sale of two HTGR's to Southern California Edison Co., and the participation of Gulf General Atomic Co. (GGA) in construction of a HTGR in West Germany.

Legislation and Government Programs.—The entire inventory of thorium held by the Government was authorized for disposal. However, there was no response to the request for bids during 1972, and thorium and its compounds were not sold from the stockpile. At the end of 1972, 1,789 tons of thorium-oxide (ThO_2) equivalent were held by the Government in stockpile.

Effective January 1, 1972, under the "Kennedy round" schedule of tariff reductions, ad valorem duties were reduced to 17.5% on thorium compounds, 6% on metal, and 7.5% on thorium alloys.

DOMESTIC PRODUCTION

Mine Production.—Production of byproduct monazite from a Pleistocene beach-sand deposit, located 35 miles inland and 10 miles fron Green Cove Springs, Fla., started in October 1972. Titanium Enterprises, jointly owned by American Cyanamid Co. and Union Camp Corp., became the second domestic monazite producer. In addition to monazite, mine products included ilmenite, leucoxene, rutile, and zircon.

Humphreys Mining Co., with its operation near Folkston, Ga., remained the largest producer of monazite in the country. Output was slightly lower in 1972. Estimated ThO_2 content remained at 5%. Heavy-mineral sands were mined by suction dredge for their titanium minerals and zircon content. The byproduct monazite was sold under contract to W. R. Grace & Co., Chattanooga, Tenn. Monazite was processed essentially for its rare earths oxide (REO) content. Thorium-bearing residues were stockpiled for processing as needed.

Humphreys Mining Co. continued land rehabilitation of an area disturbed by mining. Mill waste was used as fill, and, after grading, topsoil was respread, fertilized, and planted with grass. The company was presented with the State of Georgia first honor award for land reclamation achievements.

Refinery Production.—The principal domestic firms processing monazite for rare-earth elements and thorium were W. R. Grace & Co., at Chattanooga, Tenn., and Lindsay Rare Earths, affiliated with Kerr-McGee Chemical Corp., West Chicago, Ill. A number of thorium-processing companies maintain stocks of various compounds and the metal for nonenergy use and for nuclear fuels.

Table 1.—Companies processing and fabricating thorium, 1972

Company	Plant location	Operations and products
American Light Alloys, Inc	Little Falls, N.J	Magnesium-thorium alloy.
Consolidated Aluminum Corp	Madison, Ill	Do.
Controlled Castings Corp	Plainview, N.Y	Do.
Gallard-Schlesinger Chemical Manufacturing Corp.	Carle Place, N.Y	Processes oxide, fluoride, and metal.
General Electric Co	San Jose, Calif	Nuclear fuels.
Do	Wilmington, N.C	Do.
W. R. Grace & Co., Davison Chemical Div.	Chattanooga, Tenn	Processes domestic and imported monazite; produces oxide; stocks of hydroxide and metal powder.
Gulf General Atomic Co	San Diego, Calif	Nuclear fuels.
Gulf United Nuclear Fuels Corp	Hematite, Mo	Do.
Do	New Haven, Conn	Do.
Hitchcock Industries, Inc	South Bloomington, Minn.	Magnesium-thorium alloys.
Kerr-McGee Chemical Corp	Cimarron, Okla	Nuclear fuels.
Lindsay Rare Earths	West Chicago, Ill	Processes imported monazite; stocks of thorite; produces oxide, nitrate, and oxalate.
NL Industries, Inc	Albany, N.Y	Nuclear fuels.
Nuclear Chemicals and Metals Corp	Huntsville, Tenn	Do.
Nuclear Fuel Services, Inc	Erwin, Tenn	Do.
Nuclear Materials & Equipment Corp. (NUMEC).	Apollo, Pa	Do.
Do	Leechburg, Pa	Do.
Ventron Corp., Chemicals Div	Beverly, Mass	Metallic thorium.
Wellman Dynamics Corp	Creston, Iowa	Magnesium-thorium alloy.
Westinghouse Electric Corp	Bloomfield, N.J	Processes compounds; produces metallic thorium.
Do	Columbia, S.C	Nuclear fuels.

CONSUMPTION AND USES

Based on monazite production and foreign trade figures, apparent consumption of thorium (in terms of ThO_2 equivalent) was estimated at 300 tons during 1972. However, actual domestic industrial consumption was lower because the monazite supply was processed for its rare earth content, and most of the thorium residue remained in company holding areas.

Nonenergy industrial consumption was estimated at 100 to 150 tons ThO_2 equivalent. The major uses were in incandescent gas lamp mantles; hardener for magnesium-thorium alloys in aerospace applications; dispersion hardening of metals such as nickel, tungsten, and stainless steel; and electronic, refractory and chemical (catalytic) applications.

In the nuclear field, research and development studies continued on thorium-uranium fuels, reactor concepts for these fuels, and thorium fuels reprocessing. Thorium-uranium fuels (Th_{232}-U_{232} fuel cycle) are used in the HTGR, the molten-salt breeder reactor, and seed-blanket loadings for the pressurized water reactor.

During 1972, plans for construction of two HTGR nuclear power plants were announced. The Southern California Edison Co. signed a letter of intent with GGA, of San Diego, Calif., a Division of Gulf Oil Corp., to design and supply two 770,000-kilowatt HTGR's to be located in the eastern California desert. A site for the facility had not been selected at yearend. The first unit was tentatively scheduled for operation in 1981. Southern California Edison has also taken an option for two additional, larger capacity HTGR units that would be located at another site.

A second HTGR plant was planned by Delmarva Power and Light Co., Wilmington, Del. The new nuclear power station will consist of two 700,000-kilowatt HTGR's, and the total costs were reported to be $680 million. The site is located 15 miles south of Wilmington. Reportly, the first unit would be operational in 1979, and the second one 2 years later. GGA will design and supply the HTGR's.

Table 2.—U.S. foreign trade in thorium and thorium-bearing materials

(Quantity in pounds unless otherwise specified)

Other	252	23,253	227	28,195	151	22,811	Switzerland 118.

[e] Estimate.

[1] Includes uranium; thorium and uranium are undifferentiated in official statistics.

[2] Based on manufacture of 1,000 gas mantles per pound ThO_2.

FOREIGN TRADE

During 1972, imports of monazite largely for the rare earth content, decreased sharply (83.5%) from 1971 levels. Malaysia was the only supplier of monazite during 1972. Imports from Australia, the largest supplier in 1971, ceased during 1972. Imports of thorium oxides decreased significantly (87%), but imports of thorium nitrate were about four times higher than in 1971. These compounds were imported from France. Imports of gas mantles decreased slightly (1.6%) from 1971 levels. The United Kingdom and Austria were the principal suppliers.

Minor imports of thorium waste and scrap were registered during 1972 for the first time since 1970.

In official statistics, thorium and uranium exports are undifferentiated. Consequently, it is impossible to evaluate thorium exports only. However, the composite figure for thorium and uranium exports indicated a decrease in metal and alloy exports and an increase in exports of compounds.

WORLD REVIEW

Australia, India, Brazil, Malaysia, and the United States were the principal world producers of monazite concentrate, the main source of thorium, during 1972. No raw material was mined for recovery only of ThO_2; output of monazite and ThO_2 resulted from operations of the rare earth industry.

Brazil.—During 1972 no major changes were reported in the beach sand industry. The Commissão Nacional de Energia Nuclear (CNEN) controlled the overall production of monazite in the country. CNEN, through Administração da Produção da Monazita (APM), operated workings at Itabapoana (Rio de Janiero) and Cumuruxatiba (Bahia). Monazita e Ilmenita do Brasil (MIBRA), a privately owned company, operated facilities for the production of monazite at Guarapari.

Law 5740, enacted in December 1971, created a mixed Government-private company, Cia. Brasileira de Tecnologia Nuclear (CBTN), to operate under CNEN in certain commercial aspects of nuclear energy. The stated objectives of CBTN were reported as follows: to prospect for and mine nuclear and associated mineral deposits through the Cia. de Pesquisa de Recursos Minerais (CPRM), and the development of nuclear energy and its uses. CBTN will have headquarters in Brasilia, the company's capital will amount to $18 million. The law stipulates that only Brazilians can be directors and members of the fiscal council of the company.

Canada.—There has been no thorium production since 1968, although large thorium resources exist in Canada. Some

[e] Estimate. [p] Preliminary. W Withheld to avoid disclosing individual company confidential data.

[1] In addition to the countries listed, Indonesia and North Korea produce monazite, but information is inadequate to make reliable estimates of output levels.

[2] Year beginning April 1 of that stated.

[3] Exports.

research continued to reduce costs and produce high-purity thorium.

In addition, authorities prepared detailed proposals for legislation regulating ownership in the nuclear industry. At yearend, no information was available on the status of this legislation.

Germany, West.—During 1972, Gulf Energy and Environmental Systems Inc. (GEES) acquired a 45% interest in Hochtemperatur Reaktorbau GmbH (HTR); Brown, Boveri and Co., Mannheim, retained 55% interest in the new company. GEES as part owner will license HTR to use GGA-developed HTGR technology. In return, GEES would gain access to the technology of the thorium high-temperature reactor (THTR) with its "pebble bed" fuel concept that HTR expects to demonstrate in a prototype reactor at Schmehausen, near Dortmund.[2]

India.—According to Indian Rare Earths Ltd. (IRE), monazite production increased nearly 7% during the fiscal year ending March 1972.[3]

Production and sales data for fiscal 1971 and 1972 were as follows, in short tons:

	1971[1]	1972[1]
Monazite processed	3,903	4,165
Production of thorium hydroxide	1,378	1,499
Sales of monazite:		
Quantity	3,745	4,677
Value ... thousands	$147	$181
Sales of thorium hydroxide[2] ... do	$68	NA

[1] Fiscal year ending March.
[2] To Indian Government.

The IRE will make a feasibility study of the mineral sand deposits along the Orissa coast for assessing the monazite content. Mineral sands are found near Gopalpura, on a 25-mile stretch of the Orissa coast. If results of the study are favorable, IRE plans to build a mineral separation plant in Orissa. IRE also planned to double the capacity of the Chavara mineral sand plant in Kerala State from 110,000 to 220,000 short tons per year and to expand capacity of the Manavalakurichi plant from 55,000 to 88,000 short tons per year. The company continued to operate the thorium plant at Trombay as agent of the Government of India.[4] The company also discussed with the Department of Atomic Energy and Bhabha Atomic Research Center the details of a program of scientific cooperation with the Center for Research and Development at Trombay.

Indonesia.—The State-owned Perussahaan Negara Tambang Timah planned to extract monazite as a byproduct of tin mining. Expansion of facilities to increase tin production and separate marketable monazite concentrates was reported.[5]

Sri Lanka (formerly Ceylon).—The Ceylon Mineral Sands Corp. announced plans to expand its mineral sand facility at Pulmoddai. Equipment from the China Bay plant will be dismantled and used for the expansion. Upon completion, the new integrated sand complex at Pulmoddai will have an annual capacity of 200,000 tons of raw sand yielding 500 tons of monazite and other products. During 1972, a special committee representing the Ministry of Industries, Ministry of Irrigation, and others was formed to ensure timely construction of ancillary facilities for the project.[6]

South Africa, Republic of.—During 1972, two discoveries of monazite were reported The first indicated monazite reserves in sand dunes near Garies, Namaqualand. A concentration of heavy minerals was first noticed by airborn radiometric survey. Reserves were reported at 95 million tons of sand with a 10% content of heavy minerals. The second discovery was in the northeastern Transvaal, 56 kilometers north of Rustenburg. Production of thorium as a byproduct may be possible. Assays indicated an average content of 3.16% ThO_2.[7]

Although the heavy minerals recovery plant of Palabora Mining Co. Ltd. at Phalaborwa, Transvaal, went on stream in 1971, technical details of the operation were not reported until 1972. Tailings from the copper concentrator are used as the raw material for heavy minerals production. The six modules of the heavy minerals plant correspond to the six sections of the copper concentrator. After desliming and removal of magnetite, the entire tailings output of the concentrator is processed through the plant. About 22,000 tons per day of dry solids represents the average quantity fed to the plant. Uranothorianite concentrate, obtained by gravity concentration and containing approximately 5% U_3O_8, 14% ThO_2, and 65% ZrO_2, was processed through the chemical extraction plant. Thorium and uranium are extracted by leaching with hot nitric acid. The liquor containing thorium and uranium is then treated in a solvent extraction circuit and the product calcined. A new feature of the process is the provision of facilities for recovery of nitric acid and thorium from the barren solution or raffinate from the solvent extraction. Since the ThO_2:U_3O_8 ratio is on the order 2.5:1, thorium could become an important byproduct.[8]

United Kingdom.—The United Kingdom Atomic Energy Authority won a contract to design and supply a solid moderator reactor (SMR) for the THTR under construction at Schmehausen in West Germany. The function of the SMR is to facilitate reloading of the THTR.[9]

Venezuela.—The Government announced a discovery of thorium in the Cerro Impacto Codesur area of southern Venezuela. The area was reserved for exploration by the State through a Government-owned corporation called Promocion Del Desarrollo Del Sur de Venezuela (Prodesur). Information on size of deposits and reserves was not reported.

TECHNOLOGY

Energy and metallurgical applications together with extraction techniques were the principal subjects of studies related to thorium during 1972. Most of the research was basic, and industrial utilization of results was not imminent.

Nonenergy.—At the Elliot Lake uranium mine in Ontario, Canada, large volumes of waste materials contain thorium. An investigation was conducted to find a solvent extraction process for the coextraction of uranium and thorium. The new approach would replace the present precipitation procedure for thorium elimination, which is costly because of neutralization and coprecipitation losses of the rare earths. Results indicated that high-purity thorium sulfate can be produced with the ion exchange-neutralization route. In addition, increased revenue would result if thorium is recovered.[10]

Metallurgical research was directed toward studies determining the effects of thorium and thorium compounds on physical and chemical properties of alloys, mostly high-temperature alloys, in different environments. One investigation indicated that addition of ThO_2 to high-temperature nickel or cobalt-base superalloys slows oxidation. In an oxidation process induced by Na_2SO_4, the presence of ThO_2 in a nickel-chromium alloy promoted selective oxidation of chromium, and the growth rate of the chromium oxide layer was approximately one order of magnitude less than that for growth of chromium oxide in simple nickel chromium alloys.[11]

The application of fine wires as high-strength structural components requires a better undertanding of differences of creep behavior. The creep properties of fine, recrystallized tungsten-thorium oxide (1% ThO_2 by weight) wires were studied over the temperature range 1,800° to 2,750° C. The creep behavior of tungsten-thorium alloy wire depends on grain structure, temperature, and stress. The study showed that the creep behavior of fine wires was not affected by geometry, and identical results could be expected for larger diameter specimens.[12]

Ronson Metals Corp.'s "CerAlloy 400," made of approximately 80% thorium, 15 mischmetal, and 5% aluminum, was used in plutonium-powered pacemakers (small devices, surgically implanted in body, regulating the rhythm of heart beat). The new pacemaker should operate for 10 years without change of power source, which is now necessary every 30 months.[13]

[12] Moon, D. M. Creep of Fine Wires of W-ThO_2 Alloys. Met. Trans., v. 3, No. 12, December 1972, pp. 3097–3102.

A dispersion-modified alloy containing thorium with nickel and chromium was under development for use in the space shuttle. Necessary properties of this alloy are high-strength, formability, and good oxidation resistivity at 2,200° F. Research indicated that a 2% to 5% addition of aluminum to the base alloy improved the oxidation resistance of the basic Ni-Cr-ThO system with a loss of strength at elevated temperatures.[14]

Th-Ni systems were studied over a composition range from 50% to 96% Ni and a temperature range of 1,000° to 1,500 C. Intermetallic compounds were observed that were not previously found. Alloys in this composition range were stable in air. A few alloys were annealed for 14 days at 800° C. Th-Ni alloys showed some similarities to Th-Si alloys.[15]

Work on optical absorption spectroscopy of ThO_2 was extended to purer specimens than those used previously. The fundamental absorption edge for these specimens lies at much higher energy than the apparent edge reported previously. A full analysis of certain crystals by spark-source mass spectrometry indicated that no strong correlation existed between specific band areas and impurity-element concentration. Moreover, purer specimen of fused ThO_2 revealed new, previously unobserved bands of the ThO_2 spectrum.[16]

Behavior of thorium-carbon alloys in a nitrogen environment at moderate pressures was examined. Results indicated an "uphill" (up a concentration gradient) diffusion of carbon in the ternary solid solution Th (C,N). This explains the tendency for carbon and thorium to segregate in the course of reaction of thorium carbon alloys with nitrogen at moderate pressures.[17]

Energy.—Effects of additives on the sintering of ThO_2 and ThO_2-Y_2O_3 compacted and loose powders were studied. The investigation showed that small amounts of nickel oxide are potent and increase the rate of sintering of thorium oxide, and the major portion of densification occurs very rapidly and is followed by a much slower process of sintering.[18]

A new HTGR concept was under investigation. GGA of San Diego, Calif., negotiated a contract with the Atomic Energy Commission (AEC) for design, engineering, and construction of a nuclear gas-turbine powerplant, which would eliminate the steam-turbine cycle by combining the HTGR with a closed-cycle helium gas-turbine generator. Hot helium at 1,500° C would turn the gas-turbine generator. Benefits of the new concept include savings in capital costs, improved reactor operating efficiency, and reduced environmental impact since lesser quantities of cooling water are needed.

The light water breeder reactor (LWBR) fuel is ThO_2 pellets in which 1% to 6% U_{233} in UO_2 form is dissolved. A project was underway to develop a chemical flowsheet for converting uranium-nitrate solution to ceramic grade UO_2 powder having desired properties for uniform blending with ThO_2 powder and for pressing and sintering to high-density fuel pellets for the LWBR.[19]

Solvent properties and corrosiveness of liquid sodium, which is used as a coolant in fast-breeder reactors, were the subjects of a study originating in Sweden. A system of corrosion in liquid metals is often accompanied with mass transfer of corrosion products, and alloys form within the bulk phase of the liquid metal. The Th-Cu system was studied in the temperature range of 200° to 700° C. Reaction products are finely divided and well crystallized at temperatures below the melting points. Sodium apparently does not participate as a catalyst in the process, but does promote the reaction by activating the cooper surfaces.[20]

In connection with the chemical processing of molten-salt breeder reactor (MSBR) fuels, information was sought on mutual solubilities of thorium and certain rare earth lanthanides in bismuth solutions over a temperature range of 350° to 700° C. Although individual solubilities of thorium bismuthides and most lanthanide bismuthides are known, few data are available on their mutual solubilities or the interractions of thorium, bismuth, and the lanthanides. For the study, the system was contained in an argon atmosphere in a molybdenum crucible. The components of the system interracted to form solid compounds.[21]

Tin

By Keith L. Harris [1]

Free world supply of tin exceeded consumption by about 7,000 long tons in 1972. World mine production of tin for 1972 was 239,602 long tons, up from 232,232 long tons in 1971. U.S. consumption of primary and secondary tin taken together decreased 1% for the year, with primary tin consumption increasing 3% and secondary consumption decreasing 14%. The major uses for tin were in solder, 32%; tinplate, 31%; bronze and brass, 14%; chemicals including tin oxide, 6%; and babbitt, 4%. Tin, as the mineral cassiterite (SnO_2), is mined and smelted at many places around the world, almost totally outside the United States. Most of the nation's tin, in the form of slabs, bars, and ingots, came from Malaysia and Thailand. Less than 100 long tons of tin were mined in the United States during the year, all from mines in Colorado and Alaska. About one-quarter of the tin used in the United States in 1972 was reclaimed from scrap in about 85 secondary smelters located across the country.

The only primary tin smelter-refinery currently operating in the United States is the Texas City, Tex., facility of Gulf Chemical and Metallurgical Corp. The smelter received 4,216 long tons of tin-in-concentrate from Bolivia's State-owned Corporacion Minera de Bolivia (COMIBOL). In addition to concentrates, the smelter processed tin wastes for secondary recovery.

The Lost River Mining Corp., which has been conducting an evaluation of its fluorite-tin-tungsten deposit on Alaska's Seward Peninsula, has revised upward its tin reserves in one zone to just under 80,000 long tons. An additional 110,000 long tons have been claimed or indicated in two other zones of the property.

The General Services Administration disposed of no tin from the strategic stockpile through commercial channels, but 361 long tons were shipped to Turkey under programs of the Agency for International Development (AID).

The average New York price for prompt delivery of Straits (Malaysian) tin in 1972 was 177.469 cents per pound. This

represents a significant increase from 167.344 cents per pound in 1971.

The International Tin Council (ITC) at its regular quarterly meeting in July redetermined floor and ceiling prices for tin in the light of changes in exchange rates following the floating of the pound sterling. The market price of tin for purposes of buffer stock operations was to be expressed as the ex-works price on the Penang market.

Legislation and Government Programs.—No strategic stockpile tin was disposed of through commercial channels during the year. However, 361 long tons of tin were released to AID for shipment to Turkey. The stockpile objective remained at 232,000 long tons, and at the end of the year, there was an excess of 18,664 long tons on hand.

Government financial assistance on a participatory basis was available through the Office of Minerals Exploration (OME), U.S. Geological Survey, for tin exploration up to 75% of the allowable costs.

The depletion allowance for tin remained at 22% for domestic deposits and 14% for foreign deposits.

DOMESTIC PRODUCTION

PRIMARY TIN

Mine Production.—Domestic production of tin in 1972 was less than 100 long tons. Most of the year's output came from Colorado as a byproduct of molybdenum mining. Some tin concentrate was produced at dredging operations and as a byproduct of placer gold mining operations in Alaska. The Lost River Mining Corp., set up by Canada's P.C.E. Explorations to conduct operations at a fluorite-tin-tungsten property in the Lost River area of Alaska's Seward Peninsula, continued its feasibility study on mining and milling facilities for a 4,000-long-ton-per-day open pit mine projected to open by 1976. Reserves at the prospect area represent at least a 20-year supply. A $3 million share placement has been made to cover costs of the feasibility study. United States, Japanese, and Canadian firms have shown interest in long-term purchases and considerable financial assistance will be given by State and Federal agencies.

Smelter Production.—The only tin smelter in the United States is the Texas City, Tex., facility of Gulf Chemical and Metallurgical Corp. In 1972, it operated on Bolivian tin concentrate which formed the base load together with low-cost reclaimed domestic industrial residues to complete the feed. The smelter performed these functions as a contract toll converter for COMIBOL, and the resulting metal was then sold by COMIBOL to U.S. consumers. Thus, to all intents and purposes, U.S. tin consumers were wholly dependent upon foreign tin in 1972.

SECONDARY TIN

The United States is the world's leading producer of recycled, or secondary, tin. The United Kingdom, the Federal Republic of Germany, Austria, and Australia also produce secondary tin in significant quantities.

Of the tin recycled during 1972, 89% was an alloy constituent of bronzes,

Table 2.—Secondary tin recovered from scrap processed at detinning plants in the United States

[1] Tinplate clippings and old tin-coated containers have been combined to avoid disclosing individual company confidential data.

[2] Recovery from tinplate scrap treated only. In addition, detinners recovered 551 long tons (494 tons in 1971) of tin as metal and in compounds from tin-base scrap and residues in 1972.

brasses, solders, and bearing and type metals. A small amount also remained in chemical compounds. Only about 11% of the recycled tin, mostly from new tinplate scrap, found its way to market as metal. This latter volume provided only 3% of the total tin supplied to U.S. consumers in 1972, a proportion which does not vary appreciably from year to year.

Secondary tin furnishes 27 to 30% of the total U.S. tin supply each year. However, secondary tin produced in this country was down in 1972 by 441 long tons.

Five companies in 11 States were engaged in the detinning business in 1972. Normally the raw materials used are tinplate scrap and spent chemicals or tinning solutions.

Table 3.—Tin recovered from scrap processed in the United States, by form of recovery

[1] Includes secondary pig tin and tin acquired in chemicals.

[2] Includes pewter, britannia metal, and jewelers' metal.

plate was the largest consuming sector of primary tin (39%), the amount of total tin used for this purpose failed to be the largest domestic end-use for the first time since 1945. A 24% increase in imports of tinplate of which Japan furnished 56%, and a very small increase in shipments of steel-based cans resulted in an 11% decrease in U.S. tinplate production. An increase of over 34% in shipments of aluminum cans contributed in part to the lower consumption rate of tinplate. Consumption of tin in bronze and brass (down 13%) and babbitt (down 2%) continued the decline of the past several years. Compared with 1971 figures, the use of tin increased in alloys, bar tin, chemicals, collapsible tubes and foil, solder, tinning and white metal, while consumption for type metal was essentially unchanged. Tin consumption by U.S. brass mills was 1,426 long tons of primary tin compared with 1,065 long tons in 1971. Consumption of secondary tin, at 501 long tons, was down somewhat from the 1971 total of 545 long tons.

STOCKS

Tinplate mills, which at yearend held 65% of the plant stocks of pig tin, were the largest users of primary tin. Stocks of pig tin rose to the year high of 9,565 long tons at the end of January in anticipation of a possible dock strike in February. Stocks dropped after the strike failed to materialize. An upward trend was evident for the remainder of the year with yearend stocks of pig tin recording a 7% rise from 1971 figures reversing the downward trend in evidence since 1965. Tin in process and tin afloat recorded slight declines from 1971 but stocks held by jobbers and importers rose 67% resulting in an increase of 2% in total industrial stocks.

PRICES

The average price for prompt tin metal, at £1505.94 per metric ton, was higher on the London Metal Exchange (LME) than the average 1971 price. Prices were buoyed in midyear by the floating of the pound sterling. Prices on the Penang and New York markets retreated from high midyear prices as an ITC forecast of a deficit of 3,500 long tons in production changed to an actual surplus of 7,000 long tons by yearend. On both markets, prices in December 1972 were about the same as in January 1972. The average Penang price for ex-works Straits tin in 1972 was M$626.80 per picul (one picul = 133.33 pounds), and the average New York price for prompt Straits tin was 177.469 cents per pound.

After dull trading conditions early in the year on the Penang market, the revival of consumer demand to replenish stocks moved prices to the high of the year of M$655.50 per picul on March 24. Prices then deteriorated through August when

ITC buffer stock support held the prices at the M$622.00 per picul level. Consumer demand picked up after summer stocks were worked off and prices rose moderately from late August through September. Prices fell to the low of M$605.00 per picul in mid-November after which they recovered to end the year at M$629.00 per picul.

Source: American Metal Market.

FOREIGN TRADE

The United States continued to rely upon foreign sources for tin. Malaysia furnished 62% of the tin imported into the United States; Thailand, 22%; and Australia and Indonesia, combined, 8%.

During 1972, 4,216 long tons of tin-in-concentrate were imported from Bolivia for smelting at the Texas City, Tex., smelter.

Exports from the United States were 1,134 long tons.

Small tonnages of secondary tin enter the United States as alloy constituents in recyclable solders or other alloys or as tinplate or other scrap, dross, skimmings, and residues. These volumes find their way into consumption figures and account for the differences normally encountered between U.S. production and consumption of secondary tin. Tin that is a constituent alloy in imports and exports of babbitt, solder, type metal, and bronze is shown in the Minerals Yearbook chapters on "Copper" and "Lead." Ferrous scrap exports, including those of tinplate and terneplate scrap, are not classified separately.

WORLD REVIEW

INTERNATIONAL TIN AGREEMENT

The International Tin Council (ITC) operating under the Fourth International Tin Agreement, had an active year in the face of surplus tin production, sluggish demand, an unstable monetary base and low tin prices. Production of tin-in-concentrate exceeded consumption of tin by about 7,000 long tons. Prices of tin remained in the lower sector of the buffer stock operating range except for several months in the first half of the year when prices moved into the middle sector.

At its March meeting, the ITC announced that on December 31, 1971, the buffer stock contained 6,532 long tons of tin metal. In addition, Taiwan withdrew from membership and the consumer member votes were reallocated.

After the floating of the pound sterling by the British Government on June 23, the ITC at its July meeting temporarily changed the currency base for the operation of the buffer stock from terms of pound sterling per metric ton to terms of the ex-works price of tin on the Penang market as expressed in Malaysian dollars per picul.[2] The redetermined floor and ceiling prices and sectors of the price range, which approximated the former price range were as follows:

	M$ per picul ex-works Penang
Floor price	583
Lower sector	583–633
Middle sector	633–668
Upper sector	668–718
Ceiling price	718

The votes of the consuming countries, as established at the July meeting, effective July 1, 1972, were as follows:

	Votes
Japan	216
United Kingdom	141
Germany, West	115
France	90
Italy	60
U.S.S.R.	56
Netherlands	46
Canada	41
India	40
Poland	37
Czechoslovakia	32
Belgium-Luxembourg	29
Spain	28
Yugoslavia	16
Hungary	15
Denmark	11
Austria	10
Bulgaria	10
Korea, Republic of	7
Total	1,000

The buffer stock was reported to contain 7,971 long tons of tin metal on March 31, 1972. The first quarter installment from the consuming countries to the buffer stock of the equivalent of 2,461 long tons was paid. The first voluntary contribution to the buffer stock from a consuming country of $1.6 million was accepted from the Netherlands, and the French Government served notice that it intended to make a voluntary contribution to the buffer stock. Also, an outline report on arrangements for a proposed conference on tin to be held in the fall of 1974 at Kuala Lumpur, Malaysia, in conjunction with the Tin Research Institute (TRI) and the Malaysian Government was presented.

The ITC held a special session in August in London to discuss the possibility of imposing export controls and to request additional financial support for the buffer stock to stem the declining tin prices. The ITC rejected export controls in favor of additional support for the buffer stock in the form of an immediate callup of 4,921 long tons of tin metal or its cash equivalent from the producing nations. The ITC also granted the executive chairman authority to call up the remaining 2,461 long tons of tin metal from the 19,684 long ton aggregate compulsory contribution without the need of convening a special meeting of the Council. Support of the buffer stock proved costly for two of the members, Indonesia and Nigeria, who were forced to borrow from the International Monetary Fund (IMF).

The sixth session of the ITC was held in Djakarta, Indonesia, October 3-6. Floor and ceiling prices and sectors of the price range were reviewed and retained as established at the July meeting. Votes of the producing countries were revised and became effective October 1, as follows:

	Votes
Malaysia	441
Bolivia	181
Thailand	132
Indonesia	119
Nigeria	50
Zaire	43
Australia	34
Total	1,000

The Council again decided not to apply export controls but to arrange for a $20.8 million standby credit facility from the IMF for buffer stock purposes. Buffer stock levels for June 30 and October 5 were 7,991 and 9,971 long tons, respectively. Continuing buffer stock support for the fourth quarter failed to bring the price of tin out of the lower sector of the buffer stock operating range. Buffer stock holdings at the end of December were not revealed but they were probably about double the 6,532 long tons held on December 31, 1971. This large buildup during the year offered continued impetus to the feelings that buffer stock operations would have to be supplemented with export controls early in 1973 to move the price into the middle sector.

A conference on the consumption of tin, jointly sponsored by the ITC and the TRI was held in London in March. Seventeen tin-consuming and six tin-producing nations were represented at the 7-day conference. Papers were presented discussing tinplate and the availability, properties, marketing, and uses of tin.

Australia.—Associated Tin Smelters Pty. Ltd. increased the capacity of Australia's only tin smelter at Alexandria, New South

---

[2] One Malaysian dollar (M$) = US$0.355, one picul = 133.33 pounds.

Wales, by 50% to 15,000 long tons per year of concentrate. The expansion is part of a 5-year plan to keep pace with increasing mine production and to produce more metal within the country. Most of the exported concentrate was smelted in Malaysia and the United Kingdom.

Renison Ltd., Australia's largest tin producer, has increased its proven ore reserves to 7,149,000 long tons with an estimated tin content of 1.3%. The Aberfoyle group, consisting in part of Aberfoyle Tin Co. N.L., Ardlethan Tin N.L. and Cleveland Tin N.L., reported a mid-year total of 7,843,000 long tons of measured, indicated, and inferred ore reserves. Cleveland Tin N.L. reported an overall drop in recovery rate at their newly commissioned flotation plant from 69.3% to 67.2% because of higher throughput rates, which resulted in intense loading of individual sections.

Tableland Tin Dredging N.L. rebuilt its dredge at Upper Return Creek, Mount Garnet, Queensland. The area leased at Upper Return Creek is reported to encompass 10 million cubic yards calculated to contain 2,550 long tons of cassiterite. Upon completion of these leases, the dredge will be moved to Lower Return Creek where proven reserves of 13.25 million cubic yards containing about 2,400 tons of cassiterite are available.

Minerals Recovery (Australasia) N.L. is involved in five separate mining operations over the 16-mile stretch of its Vegetable Creek-deep lead prospect near Glen Innes, New South Wales. A 30-cubic-yard-per-hour plant at its Sugarloaf open pit mine and a 100-cubic-yard-per-hour plant at its Foleys open pit mine were commissioned. Loloma Mining Corp.'s Irvinebank tin operation in North Queensland commenced continuous milling in April. Treatment capacity was projected at 65,000 long tons per year. Gippsland Minerals N.L. and Cominco Exploration gave inferred ore reserves at their jointly held Queen Hill, Zeeham, Tasmania property as 1 million long tons of 1.4% tin and 200,000 long tons of 0.8% tin.

Bolivia.—Of the 31,056 long tons of tin-in-concentrate produced in 1972, COMIBOL contributed 21,246 long tons, the medium miners 5,832 long tons, and the small miners 3,978 long tons. COMIBOL'S marketable tin output, up 6.3% from that of 1971, originated mainly from ore containing 0.76% tin, but also included purchases from independent small miners and from lessees and cooperative organizations working COMIBOL'S small mines, and tin as a volatilization product from several plants. COMIBOL'S costs to produce and market tin continued to rise, reaching $1.61 per pound in 1972 compared with $1.58 in 1971 and $1.50 in 1970. After the Bolivian currency devaluation of October 27, 1972, the costs in November and December decreased to $1.37 and $1.30, respectively. However, a new 20% tax on the value of exported tin imposed at the time of devaluation added 19 cents to the cost. The most important COMIBOL mine, Siglo XX, which produced about 32% of COMIBOL'S tin output, reportedly is running out of low-grade tin mineralized blocks which it mines by block-caving methods. This mine's largest tin reserve exists in its mill tailings.

Total tin exports were 30,087 tons, the largest tonnage of tin exported since 1953 when 34,824 tons were exported. The Empresa Nacional de Fundiciones (ENAF), the national smelting company, decreased its metallic tin exports from 6,706 tons in 1971 to 6,200 tons in 1972, but the value was about the same as that of 1971 exports because of increased prices.

Early in the year COMIBOL and International Metal Processing Corp. (IMPC) agreed to form a joint venture company Empresa Metalúrgica Boliviana S.A. (EMBOSA) to operate the tin tailings concentration plant at Catavi with COMIBOL owning 55% of EMBOSA and IMPC 45%.

COMIBOL estimated its ore reserves at about 300,000 tons of contained tin as of January 1, 1972. These reserves do not include alluvial deposits, or tailings and dump materials that may be processed in the future.

Representatives from Klöckner-Humboldt-Deutz of West Germany and ENAF discussed plans to increase the annual capacity of the Vinto smelter from 7,400 tons to 19,700 tons, but no final decision was reached. In December it was reported that the planned capacity had been reduced to 10,800 tons because of the high estimated cost for the larger smelter. ENAF has operated the plant for 2 years but has not overcome the problem of low tin recovery. In addition to ENAF's smelter there are two small tin smelters in Oruro; the Pero smelter which was returned to the Pero family by COMIBOL late in 1972 and Metalúrgica Oruro. Both smelters produce a volatilization product. Another small smelter, Hormet, in La Paz produced a very small amount of metallic tin.

Michimen Co., Ltd., and Senju Metal Industry Co. of Japan signed a contract with ENAF to buy 590 long tons of electrolytic tin as a trial purchase to estimate the market. If successful, Japan will consider establishing a tin industry in one of the Andean Pact countries using Bolivian electrolytic tin.

The General Manager of COMIBOL signed agreements in the U.S.S.R. for the installation of a tin volatilization plant at Potosí and an $8 million loan for mining equipment. Plans called for plant construction to begin in April 1973 with completion by June 1974. It was also agreed to examine the possibility of installing at a later date tin volatilization plants in Oruro and Quechisla.

Brazil.—Twelve different groups, including 96 different companies, have applied for permission to prospect and mine the cassiterite deposits in Rondônia. Mineração Aracazeiro, Mineração Brumawdinho, and NL Industries, Inc., will jointly mine property in the upper Candeias River basin. An initial reserve of 10,000 long tons of tin has been established in the 74,130-acre

[e] Estimate. [p] Preliminary. [r] Revised.

[1] Data derived in part from the Statistical Bulletin of the International Tin Council, London, England.

[2] Includes tin content of alloys made directly from ores.

[3] Tin content of production from Metabol and Pero smelters plus exports by ENAF smelter.

[4] Estimate according to the 59th annual issue of Metal Statistics (Metallgesellschaft).

[5] Includes small production of tin from the smelter in Singapore.

area allotted to this group of companies for exploration. Two additional areas at Garcas and Candeias are being prospected for their reserve potential. The tin will be mined with a mobile excavating plant at a monthly production rate of 100 long tons of tin concentrate.

Canada.—Ecstall Mining, Ltd. a subsidiary of Texas Gulf, Inc., proved the feasibility of tin recovery from zinc tailings at its Kidd Creek mine near Timmins, Ontario. The new tin recovery circuit will go into operation late in 1973 with an expected recovery rate of 1.5 million pounds of tin per year. The Sullivan Mining Group reported discovery of a large mineralized area in Brunswick Tin's North-Zone in addition to the already defined Fire Tower Zone to the south.

Indonesia.—A contract for the expansion of the Peltim smelter at Muntok has been signed with Paul Bergsoe & Son of Glostrup, Denmark, in partnership with S. C. Pearce & Associates of Southport, Lancashire, United Kingdom. The agreement calls for improving the performance of the three existing rotary furnaces, and the construction of three stationary furnaces to increase total smelter capacity to about 27,500 long tons of refined tin per year. Trial runs are expected to begin in mid-1974.

Foreign investors are welcome in tin mining and the Government has opened the following areas for exploration and development: northern part of Riau Archipelago, excluding Karimun and Kundur; southern part of the Riay Archipelago, except Singkep; the open sea between Singkep and Bangka Island; selected areas on Bangka and Bilitung areas around Karimata; and some land group areas of Bangkinang on Sumatra.

A loan from the Netherlands was of great assistance to the program of modernizing and rehabilitating Indonesia's fleet of bucket dredges. The Mining & Transport Division (MTD) of IHC Holland of Rotterdam undertook the project to modernize three small bucket dredges, namely Klantji, Lais, and Rajah. The 9-cubic-foot dredge Klantji was the last of the steam-fired dredges, and the 7-cubic-foot dredges, Lais and Rajah, were the oldest of Indonesia's fleet of 30-tin dredges. Electrification of the Rambat and Templiland dredges doubled their capacity.

Overseas exploration companies continued their prospecting. P.T. Koba Tin was prospecting on Koba Island and the offshore areas. P.N. Timah and N.V. Billiton Maatschappij were prospecting off Air Kantung to depths of 250 feet. Billiton holds two concessions: Karimata, southwest of Kalimantan, and Pulau Trudju off the east coast of Sumatra.

Bluemetal Industries Ltd. of Australia completed negotiations with the Indonesian Government regarding tin mining on Bangka Island where substantial new reserves have reportedly been proved.

Malaysia.—Malaysia continued to lead the world in production and smelting of tin in 1972. A total of 75,617 long tons of tin-in-concentrate was mined, the highest output in 31 years. At yearend there were 56 tin dredges, 940 gravel pump mines, and 46 opencast, underground, and other miscellaneous mines in operation, a slight decrease compared with 1971 figures.

Gravel pump operations, worked for the most part by the same families that own the mines, accounted for about 55% of the concentrate produced, while dredging by corporations furnished another 32%. Opencast mines brought in 4% of the ore produced; underground mines accounted for 3%; and the remaining 6% came from miscellaneous sources. Metal production, at 89,564 long tons, was 4% above the 1971 level of 85,719 long tons and the largest amount of tin refined since 1941.

The Malaysian Government opened up 86,000 acres of virgin land in West Malaysia for tin exploration. The 40,000-acre site in the state of Johore, 36,000 acres in Pahang and 10,000 acres in Perak have unknown tin value but the Malaysian Government was confident that rich deposits would be uncovered.

Berjuntai Tin Dredging Berhad, the largest tin dredging operator in the world, increased its tin concentrate output by 714 long tons to a record of 4,917 long tons in its fiscal year ending April 30. This output is the second highest recorded of any private tin mining company in the world. Berjuntai dredges in an area about 20 miles from Kuala Lumpur on the Selangor River.

The Pehang Consolidated Co. Ltd., Malaysia's only significant lode tin producer, reported an output of 2,632 long tons of tin concentrate averaging 71.1% tin during its fiscal year ended July. Further expansion of production at the Sungei Lembing mine, principally for improvements in mining and dressing equipment and expenditures on the Gakak shaft, has been announced.

State and private interests have drawn plans to locate four new dredges in Selangor. Two dredges are planned by the Selangor State Development Corporation for a 1,000-acre site at Ulu Langat; one is planned by Petaling Tin Berhad at Kuala Langat; and Berjuntai Tin Dredging Berhad considered replacement of its 35-year-old No. 1 dredge with a new and more modern plant.

Pernas, the Malaysian state corporation, has been granted exploration rights for tin off the west coast of West Malaysia along the states of Selangor, Perak, and Penang. Pernas began a soil study in the Johore River estuary, covering 12,600 acres, using seismic profiling and core sampling to produce a geochemical map that would indicate areas for final evaluation.

Malaysia, Indonesia, and Thailand signed an agreement to draw up continental shelf boundaries in the northern part of the Straits of Malacca. The agreement will not isolate areas of seabed for exploration but will promote joint efforts in exploring areas of potential wealth for mutual benefit.

Kuala Lumpur has been chosen as the headquarters of the Tin Industry Development and Research Center for Southeast Asia. The functions of the Center would include the investigation of problems relevant to exploration, evaluation, and exploitation of the area's tin deposits. A determination of the requirements of the Center will be conducted under the auspices of the United Nations Development Program, which will assist in the establishment of the Center.

Nigeria.—Production of tin in Nigeria declined to 6,625 long tons, its lowest level since 1959. Rising costs of production, lower quality ore bodies and declining world prices all contributed to the low output. One of the declared aims of Nigeria's National Development Plan (1970–74) was fulfilled by the creation of a national mining body, the Nigerian Mining Corp. The corporation will engage in prospecting, mining, and refining of all minerals other than coal and petroleum. The Nigerian Government also set aside about $7 million for the mining sector during the current development plan to increase exploration of tin and other minerals. A wholly owned Nigerian mining company, the United Nigeria Miners Co. Ltd., formed by the All-African Miners Association, will be established in Jos to focus on tin mining. Gold and Base Metal Mines, Ltd., may become the first lode tin mining operation in Nigeria. Initiation of the operation is contingent upon the satisfactory outcome of discussions with the Nigerian Government. The company's Liruie lode, located in Kano State, Northern Nigeria, is expected to provide 600 long tons of ore per day to yield about 1,000 tons of tin concentrate per year. Indicated ore reserves were 2 million long tons. If the anticipated production rate materializes, the company would be second only to Amalgamated Tin Mines of Nigeria Ltd. in tin concentrate output. Amalgamated Tin Mines reported production of 3,720 long tons of tin concentrate for 1972, up 0.5% compared with 1971.

South Africa, Republic of.—New flotation plants were commissioned by both major South African tin companies. Rooiberg Minerals Development Co. Ltd. installed flotation equipment at their "A" mine concentrator in the Warmbaths district of Transvaal. Monthly production of tin in low-grade flotation concentrate increased to about 18 long tons by the end of the year. A production increase of nearly 4% to 1,480 long tons was reported by Rooiberg for its fiscal year ending June 30. Union Tin Mines Ltd. reported that the second stage of its two-stage flotation plant will increase its monthly recovery rate to at least 20 long tons of tin in flotation concentrate.

Thailand.—Thailand's Mineral Resources Department reported that 620 tin mines were in operation at the beginning of 1972. Of the total, there were 22 dredges (16 inland, 6 offshore), 263 gravel pumps, 16 hydraulic mines, 112 ground sluicing operations, 176 tin-tungsten operations, and 31 unspecified operations.

The largest U.S. firm with interests in Thai tin was Union Carbide Corp., which operates in Thailand through two partially owned subsidiaries, Thailand Exploration and Mining Co., Ltd. (Temco) and Thailand Smelting and Refining Co., Ltd. (Thaisarco). N. V. Billiton Maatschappij of the Netherlands owns 50% of Thaisarco and 40% of Temco. Thaisarco, which operates the only tin smelter in Thailand, experienced a 4-week breakdown in one furnace while another furnace was being renovated. Total tin metal production was not affected by the breakdown of the Phuket smelter, which reported about a 3% increase in metal production compared with 1971.

Temco's suction cutter dredge, the Temco II, which began seabed mining between Phuket Island and Tai Muang, and its smaller sister dredge Temco I, are expected to raise Temco's metal output to 1,000 long tons per year.

Satisfactory results for two other offshore dredging companies operating in Thailand have been reported. Aokam Tin Berhad's two dredges, currently recovering about 2,000 long tons of 76% tin concentrate per year, operated on the Bang Tao Bay property from November to April, and on the Phuket Bay property for the other months. Ore reserves at both areas are expected to be depleted in about 15 years. Tongkah Harbour Tin Dredging Berhad's sea dredge produces over 900 long tons of concentrate. Reserves are said to be sufficient for the life of the existing plant.

Pacific Tin Consolidated Corp., another U.S.-owned corporation in Thailand, in a joint venture with Thai Tin and Tungsten Corporation, reported satisfactory progress on the preliminary development of an underground mine near Sichon. Adits, drifts, and surface exposures have shown grades on the order of 1.4% tin in widths averaging about 7 feet.

Singapore.—The Straits Trading Co's. Pulau Brani smelter, which began refining tin in Singapore in 1890, closed down. In recent years, Pulau Brani has been treating imported tin slags until the Straits Trading Co. was advised that the site was required for further expansion of port facilities.

U.S.S.R.—The U.S.S.R. announced completion of a major tin ore dressing plant located in the Sikhote Alin Mountains, in the southern region of the Soviet Far

East. The plant will produce metal from previously discarded materials provided by more than 500 tin ore deposits in the area. An ore dressing complex at Khrustalninsk in the Soviet Far East produced a high quality tin concentrate (80% tin content) with the aid of chemicals.

United Kingdom.—Wheal Jane Ltd., a subsidiary of Consolidated Gold Fields, Ltd., produced tin metal at an annual rate of about 1,800 long tons, approximately 400 long tons over its initial target rate. Modifications of the treatment plant considerably reduced high tin losses experienced during startup. Deepening and reequipping of the Clemow shaft, to be completed early in 1973, will allow the treatment plant to operate at full capacity.

TECHNOLOGY

A new process for extracting tin from low-grade complex ores, iron-tin alloys, mattes, drosses, and slags has been developed.[3] The process using a feed containing at least 3% tin, allows the separation and recovery of the lead and iron fraction and recovery of at least 95% of the tin.

A process was patented in West Germany on an improved and cheaper chlorine volatilization process for recovering tin from ore, concentrate, or slag.[4] Calcium chloride and carbon are used in a high throughput method to form tin chloride. The gases are passed through water yielding tin oxide, hydroxide, or oxychloride. The calcium chloride is recovered and reused to briquet the input tin material.

A radioisotope X-ray fluorescence method is being used to monitor the tin content of the tailings streams at the Geevor mine in Cornwall.[5] Its basic techniques are said to be applicable to all mineral dressing plants.

A new tin oxide for polishing plastic lenses and other plastic specialties has been developed by M & T Chemicals, Inc.[6] The company claims the tin oxide polishes up to 40% faster and at 33% less cost than other available polishing materials. The firm has also developed a low-cost acid tin plating process which produces a brilliant through satin range of coatings.[7] Another development in the plating industry has been a bright tin-lead plating process which is of particular value in the electronics industry.[8] Several proprietary processes using various types of brighteners, surface active agents, and antioxidants produce a bright tin-lead coating over a wide range of current densities and temperatures.

It was found that sintering austenitic stainless steel (18% chromium, 10% nickel) with tin powder improved its tensile strength but reduced its ductility slightly.[9]

Tin powder particle size distribution had no effect on the sintering behavior of iron compacts containing 2% tin—3% copper but reduced the tensile strength of iron compacts containing 1% tin—1.5% copper.[10]

The British Cast Iron Research Association described how additions of tin can be made to cast iron to improve tensile strength and hardness.[11] The first International Standard was defined for electroplated coatings of 65/35 tin-nickel alloy on steel or iron, copper and copper alloys or zinc alloys.[12] The standard prescribes required coating thickness for various degrees of service conditions and indicates the requirement for undercoats where applicable.

A new series of polyvinyl chloride (PVC) stabilizers, polymeric dialkyltin cycloaliphatic dimercaptides, has been developed that is reported to produce rigid

PVC with improved clarity that is easier to process.[13]

A catalytic system using dehydrated granular gels of tin (IV) oxide co-precipitated with vanadate was found effective in catalyzing the oxidation of carbon monoxide.[14] This process could be of importance in treating automobile exhaust gases to render them nontoxic.

Organotins, especially the trialkyltins, have shown increasing applicability in slow release pesticides.[15] With further research these pesticides may become competitive with or more effective than organophosphorus and halogenated hydrocarbon insecticides.

Titanium

By F. W. Wessel[1]

In 1972 production of rutile in the United States was reported for the first time in several years. Titanium Enterprises, Clay County, Fla., began in midsummer to produce rutile and other heavy-sand minerals. Rutile imports, almost entirely from Australia, were 9% less than in 1971. Imports of ilmenite were 35% lower, but imports of Sorel slag were 13% higher. A plant to produce 185,000 tons per year of ilmenite concentrate was under construction in New Jersey, and was expected to come onstream early in 1973. For the first time "synthetic" rutile made from ilmenite became a market factor; imports were from Australia and Japan.

Strong demand for titania pigment continued unchecked throughout the year. The demand was based on several factors, foremost of which were an active building construction and housing market and the necessity of replacing at least part of the void left by cessation of composite pigment production. Production of titania pigment increased only slightly, and imports were obtained to meet the demand. West Germany, Canada, Japan, France, Finland, and the United Kingdom were the major sources. There were some domestic price increases about midyear, but price controls and previously concluded contracts were inhibiting factors. Two major European producers also increased prices during the year, reflecting spreading shortages.

The general titanium metal situation showed slight gains over 1971. Production of titanium sponge was resumed in February and increased steadily through August, when it reached its yearend level at about one-third of industry capacity. Recovery was assisted in some measure by Federal stockpile contracts, concluded in June with two major producers. Production of ingot increased 10%, and mill products shipments increased 12%. Consumption of sponge, scrap, and ingot showed increases of 8%, 27% and 14%, respectively. Early in the year fabricators increased mill product prices by 8%.

Legislation and Government Programs.—The stockpile objectives for rutile and titan-

---

[r] Revised.
[1] Includes a small quantity of rutile.
[2] Includes titaniferous slag.
[3] Mine shipments withheld to avoid disclosing individual company confidential data.
[4] Nominal. Actual sales probably in $1.10–$1.20 range.

ium sponge metal remained at 100,000 tons and 33,500 tons, respectively. Government inventory of rutile at yearend was 56,525 tons. Total stockpile inventories of sponge metal at yearend were 35,015 tons, of which 8,514 tons are of substandard grade and available for disposal.

The General Services Administration (GSA) about midyear concluded identical contracts with Titanium Metals Corporation of America and RMI Co. for 6,500 tons of titanium sponge, to bring stockpiled material up to the 33,500 ton objective. Each firm will deliver 3,250 tons over a 2-year period, and will be reimbursed entirely in the form of various materials excess to the stockpile and authorized for disposal.

Government exploration assistance for rutile, available through the Office of Minerals Exploration, U.S. Geological Survey, remained at 75% of the approved cost of exploration. The depletion allowance for ilmenite and rutile remained at 22% for domestic deposits and 14% for foreign deposits.

DOMESTIC PRODUCTION

Concentrates.—Production of titanium-mineral concentrates in 1972 remained essentially unchanged from the 1971 level, while shipments increased 2.2% in gross weight and 6.0% in titanium content. The average grade of concentrates shipped has been increasing for several years, and now stands at 56.5% TiO_2. Producers were E. I. du Pont de Nemours & Co., Starke and Highland, Fla.; Titanium Enterprises, Green Cove Springs, Fla.; Humphreys Mining Co., Folkston, Ga.; SCM Corporation, Glidden-Durkee Division, Lakehurst, N.J.; and NL Industries, Inc., Tahawus, N. Y.

Rutile was produced for the first time since 1968. Titanium Enterprises, jointly held by American Cyanamid Co. and Union Camp Corp., began operation in mid-1972, producing rutile, ilmenite, and zircon. Nominal capacity of the plant is 140,000 tons of heavy-sand concentrate annually.

In April the Dravo Corp. began construction of a $10 million facility to mine and process ilmenite–bearing sands in Manchester township, Ocean County, N. J. The plant will consist of a floating suction dredge and land-based wet and dry concentrators. American Smelting and Refining Co. owners of the property, expect the plant to come onstream during the second quarter of 1973. They have a 10-year contract to supply ilmenite to du Pont's chloride-process titanium pigment plants at the minimum rate of 125,000 tons per year.

In June, Titanium Minerals, Inc., announced its intention to mine rutile and ilmenite in Nelson County, Va. A pilot plant was to be built to prove out the amenability of the ores to processing.

Ferroalloys.—Production of ferrotitanium of all grades was under 1,000 tons, as steel companies increased their use of off-grade titanium metal. Producing companies were Shieldalloy Corp., Newfield, N.J., Union Carbide Co., Niagara Falls, N. Y., and Foote Mineral Co., Cambridge, Ohio. The alloys were made variously from scrap, slag, and mineral concentrates.

Metal.—Production of titanium sponge was 1% higher than in 1971. Producing companies were Titanium Metals Corporation of America (TMCA), Henderson, Nev., owned by NL Industries, Inc., and Allegheny Ludlum Steel Corp.; and RMI Co., Ashtabula, Ohio, owned by National Distillers & Chemical Corp. and U.S. Steel Corp. A third former producer, Oregon Metallurgical Corp., while still producing ingot, did not reactivate its sponge plant.

TMCA resumed sponge production in February and RMI Co. in April. Production increased steadily throughout the year; of the total 1972 output, 72% was produced during the second half. Deducting the quantity delivered to the stockpile, second half production was still more than double that of the first half.

Production of titanium ingot was 20,267 tons, an increase of 10% over the 1971 level. As in 1971, nine companies produced ingot; these were:

Company	*Plant Location*
Crucible Steel Co. of America	Midland, Pa.
Howmet Corp	Whitehall, Mich.
Martin Marietta Aluminum, Inc.	Torrance, Calif.
Oregon Metallurgical Corp	Albany, Oreg.
RMI Co	Niles, Ohio
Teledyne Titanium, Inc	Monroe, N.C.
Titanium Metals Corporation of America.	Henderson, Nev.
Titanium West, Inc	Reno, Nev.
TiTech International, Inc	Pomona, Calif.

Pigment.—Heavy demand for both rutile and anatase grades of titania pigment became evident in February and continued unabated throughout the year. Production consequently increased 1.5% over 1971 volume, and shipments about 10%. Rutile-type pigment amounted to 70% of total production, and was produced by all seven manufacturers. Anatase-type pigment was made by five companies. NL Industries closed their composite pigment plant in St. Louis early in the year, ending domestic production of this material. At the yearend, companies producing titania pigment, and their plant locations, were as follows: American Cyanamid Co., Savannah, Ga.; Kerr-McGee Chemical Corp., Hamilton, Miss.; E. I. du Pont de Nemours & Co., Antioch, Calif., Edge Moor, Del., and New Johnsonville, Tenn.; NL Industries, Inc., Sayreville, N. J., and St. Louis, Mo.; New Jersey Zinc Co. (a Gulf & Western Industries unit), Gloucester, N. J., and Ashtabula, Ohio; SCM Corporation, Glidden-Durkee Division, Baltimore, Md.; and Sherwin-Williams Chemical Co., Ashtabula, Ohio. The New Jersey Zinc Co. plant at Ashtabula was leased from Cabot Titania, Inc., late in May, with an option to buy.

During the period June 1, 1971, to January 31, 1972, four domestic titania pigment production plants were closed; total capacity lost amounted to 124,000 tons. New capacity coming onstream during 1972 was limited to du Pont's 30,000-ton expansion at New Johnsonville, where production began late in March. An additional 45,000 tons of capacity is to be installed at New Johnsonville, and will come onstream at intervals during 1973; the first 15,000 tons added production is expected in the second quarter. Plans for unspecified additional capacity at the Kerr-McGee plant were reported.

A 17-week strike at the St. Louis plant of NL Industries ended in July. However, loss of production was small because supervisory personnel operated the plant at about 80% of normal output.

Welding Rod Coating.—A total of 245,000 tons of welding rods containing titaniferous materials in their coatings was produced. Of the total output, 32% contained rutile, 46% contained ilmenite or leucoxene, 7% contained a mixture of rutile and manufactured titanium dioxide, 10% contained manufactured titanium dioxide alone, and 5% contained titanium slag and miscellaneous mixtures.

CONSUMPTION AND USES

Concentrates.—Consumption of ilmenite and Sorel slag was 12% lower and 84% higher, respectively, than in 1971. Both are used almost entirely to make titanium dioxide. Consumption of rutile increased 5% during the year.

Metal.—Consumption of sponge and ingot increased 7.6% and 14.3%, respectively; mill products shipments increased 12.3%, indicating a general, if modest, market improvement. A comparison of end uses[2] indicates the increased application of titanium in industry and commercial aircraft, in percent:

	1961	1971
Military and space uses	81	38
Commercial aircraft:		
Airframe	4	15
Engine	10	31
Industrial uses	5	16

Strikes during part of January at the mill products plant of TMCA at Toronto, Ohio, and during January and February at the mill products plant of RMI Co. at Niles, Ohio, resulted in a 20% reduction of shipments during those 2 months.

Titanium is being used in the gas turbine engines under construction for use in the U.S. Navy's Spruance-class destroyers. Each vessel will have four engines; each engine will contain at least 690 pounds of titanium. Nine vessels of an expected total fleet of 30 have been authorized. Titanium cathodes are being used increasingly as starting sheets in copper electrorefining.

Scrap consumption increased 27% in 1972. Some shortage appeared during the last 4 months as a result of decreased ingot

r Revised.

production between September 1971 and February 1972.

Pigments.—Although production increased only about 1.5%, shipments increased 8% to 10% over 1971 levels, based on preliminary figures. The excess of shipments over production represents delivery of imported material and withdrawal from producers' inventories. The manufacture of paper, rubber, and plastics each accounted for a somewhat increased proportion of the total consumed.

STOCKS

In 1972, stocks of rutile in the United States declined 34% to 157,425 short tons. Ilmenite inventories were 20% less than in 1971, but stocks of titanium slag, at 157,731 tons, were 46% higher. Yearend stocks of titanium sponge were 1,816 tons, one-third less than at yearend 1971, and scrap inventories stood at 4,375 tons, a 9% decrease. Industry stocks of titanium dioxide were estimated at yearend to be 48,250 tons, a decrease of 38,600 tons during the year.

Table 7.—Stocks of titanium concentrates in the United States, December 31

(Short tons)

e Estimate. r Revised.

PRICES

Concentrates.—No price quotations for domestic (60% TiO_2) ilmenite were available during 1972; any such figure would be nominal since mines are captive and no ilmenite is sold on the open market. Imported material of 54% content was quoted by Metals Week throughout the year at $22–24 per long ton, bulk, at Atlantic coast ports; the same concentrate brought A$10.50–A$11.50 f.o.b. Australian ports. Indian ilmenite (58 to 60%) was quoted at the equivalent of US$9.75 f.o.b. Indian west coast ports. Malayan ilmenite (52% to 54%) was quoted at yearend in the range of £9.35 to £11.32 per metric ton c.i.f. British ports.

Rutile, bulk, f.o.b. cars at Atlantic and Great Lakes ports ended 1971 at $185 per short ton but fell to $175 early in 1972; this price was maintained throughout the yearend. Australian prices for rutile were weak during much of the year, falling from A$145–A$155 in mid-1971 to A$110–A$120 in April 1972, and rising to A$115–A$125 later in the year.

Titanium slag (70%–71% TiO_2) held to the price of $50 per long ton, f.o.b. Quebec, throughout the year.

Manufactured Titanium Dioxide.—In view of continued strong demand, considerable upward price pressure developed during the year. About midyear, Kerr-McGee Chemical Corp. raised its price for rutile-type pigment 2 cents per pound, and the Glidden-Durkee division of SCM Corp. raised both rutile and anatase grades 1 cent. American Cyanamid Co. raised its price for rutile and wet-milled anatase 1 cent per pound, effective August 1; NL Industries announced a similar increase at about this time. Accordingly, in August a three-level price structure existed, at least for the rutile grades: Kerr-McGee at 28 cents, American Cyanamid, NL Industries, and SCM at 27 cents, and du Pont, unchanged, at 26 cents. Effective December 11, du Pont raised its price for paper-grade anatase 1 cent per pound, and New Jersey Zinc Co. announced a similar increase effective Jan. 1, 1973. The increases were reflected abroad; British Titan Products, Ltd., and its French affiliate, Tioxide, and the NL subsidiary Kronos, in Belgium, each announced a 7% rise in price.

Closing 1972 prices, reflected in the Chemical Marketing Reporter for Apr. 16, 1973, were as follows:

	Price, cents per pound
Anatase:	
20-ton lots, bags, freight allowed	27–28½
20-ton lots, bags, paper grade	23–24
Slurry, 50 tons (dry TiO_2 basis) in railcars, f.o.b. plant	22½–23½
Rutile:	
Regular grades, 20-ton lots, bags, freight allowed	26–28½
Nonchalking grade, 20-ton lots, bags, freight allowed	27–29½
Bulk, 65-ton lots, in railcars, f.o.b. plant, 1 cent per pound less than above quotes.	

Metal.—Sponge imported from Japan and the United Kingdom was quoted in the range of $1.20–$1.25 per pound throughout the year. Domestic sponge continued to be quoted at $1.32; however, it is believed that most sales during 1972 took place in the $1.10–$1.20 range.

FOREIGN TRADE

Titanium dioxide exports in 1972 amounted to 10,335 short tons, 39% of the 1971 quantity, reflecting the strong domestic demand. Of the total, 31% went to Canada, 16% to the Republic of Korea, 16% to European nations, and 13% to Japan. Value of the titanium dioxide exported was $4.9 million. Exports of 3,510 tons of sponge, waste, and scrap, valued at $2.2 million, was about twice the 1971 figures; 40% went to the United Kingdom, 32% to Italy, and 15% to Belgium. Wrought titanium and semimanufactures exported totaled 1.1 million pounds valued at $6.3 million; principal destinations were Canada 46%, the United Kingdom 18%, other EEC nations 20%, and Japan 5%.

Imports of ilmenite from Australia dropped 35% to 14,334 short tons, valued at $142,200. Imports of Sorel slag from Canada, at 169,327 tons, increased 13% above 1971 receipts, and were valued at $7.5 million. Rutile was received from Australia in about the same quantity and value as in 1971. Imports of sponge, waste, and scrap titanium totaled 4,173 tons, mainly sponge from Japan (56%) and the U.S.S.R. (34%). The Japanese material was valued at $4.25 million, or 91 cents per pound, and the Soviet sponge at $2.1 million, or 75 cents per pound. France and the United Kingdom were the principal sources of 181,326 pounds of ferrotitanium of various grades, valued at $75,561.

Heavy imports of titanium dioxide featured 1972; the total was 86,379 tons valued at $33.4 million. Major suppliers were West Germany (28%), Canada (20%), Japan (13.5%), France (12%), the United Kingdom (9.5%), and Finland (9%). Imports accounted for 10.7% of domestic demand, and were about double the 1971 receipts.

Imports of synthetic rutile (beneficiated ilmenite) were of interest in 1972; a total of 9,200 tons of experimental product entered the country, 8,750 tons from Australia and the balance from Japan. Valuations were at $90 and $60 per ton for Australia and Japan, respectively.

[1] Less than ½ unit.

WORLD REVIEW

Australia.—The market for titanium minerals, particularly rutile, was rather weak throughout the year, with a firming trend noticeable near yearend. Moderate demand for concentrates and revaluation of both Australian and U.S. currencies combined to make 1972 a year of lower profits and two actual failures. Mines also complained of excessive responsibility for sand stabilization.

Litigation concerning the Eneabba claims continued during the year. In any case, it seemed clear that Allied Minerals N.L. would control enough of the deposit to proceed with development. About midyear, the 55% interest that had ben held by A. V. Jennings Industries (Australia) Ltd. was relinquished; Allied Minerals, backed by Westralian Oil N.L., sought a new partner, which shortly was announced as du Pont (Australia) Ltd. Du Pont's initial investment was A$1.75 million, plus the cost of a pilot-plant operation, in return for a 25% interest in the joint venture.

The plant of Coastal Rutile, Ltd., of Queensland, was purchased by Allied Minerals from the receiver for A$114,000, moved to Eneabba, and reerected. Its capacity there will be 7,000 tons of rutile and 28,000 tons of ilmenite annually. If successful, six additional units of similar capacity will be erected. No metallurgical difficulties are foreseen, with one possible exception: The heavy minerals are coated with a siliceous clay.

At yearend the new venture was christened Allied Eneabba Pty., Ltd. E. I. du Pont de Nemours & Co. contracted for delivery of 200,000 tons of ilmenite per year to its chloride-process pigment plants.

In addition to Coastal Rutile, Ltd., Naracoopa Rutile, Ltd., was also placed in receivership, and its rutile-zircon operations on King Island, Tasmania, sold to Buka Minerals, Ltd. The new management expects to begin operations early in 1973 at 10,000 tons of rutile and 5,000 tons of zircon per year. Operations were also suspended at the Matthew Flinders rutile-zircon operation near Yamba, New South Wales, by the Dillingham Mining Co.

A joint venture of Mining Corp. of Australia and Kamilaroi Mines, Ltd., is drilling sands at Jurien Bay, near Eneabba, to delineate a rutile-zircon-ilmenite body. Late in the year it was announced that enough reserves had been measured to support annual production of up to 25,000 tons of rutile, 30,000 tons of zircon, and 130,000 tons of ilmenite.

Cudgen R. Z. and its subsidiary, Consolidated Rutile, are considering integration of operations and of financial arrangements. Such a merger would make the resulting company Australia's third largest producer of rutile and zircon.

Interest in processes to convert ilmenite to rutile remained high. Western Titanium N.L. reportedly was proceeding with construction of a A$5.75 million plant at Bunbury, Western Australia, which will have initial capacity of 30,000 tons per year. Target date for full operation is late 1974 or early 1975. Expansion to 100,000-tons-per-year capacity is contemplated. Western Titanium continued shipping products from its pilot plant during the year.

Belgium.—The 22,000-ton-per-year titanium dioxide plant of Bayer N.V., subsidiary of Farbenfabriken Bayer A.G., at Antwerp resumed production in March; an explosion in a tumbler had interrupted operations.

Brazil.—The carbonatite formation at Tapira, Minas Gerais, long known to contain columbium minerals and phosphate, has recently been surveyed as a titanium source by the National Department of Mineral Production (DNPM). Reserves are reported at 1.6 billion tons of ore at 10% TiO_2 or more. Much of the titanium content appears to be in the less common mineral anatase, which may be concentrated to a purity approaching that of rutile. The undesirable colorizers chromium and vanadium are absent.

Canada.—Canadian Tiron Chemical Corp. is developing a pilot plant in the Montreal area that will be directed toward making rutile from ilmenite. The process was not described, but it is said to use hydrogen as a reductant.

France.—Thann et Mulhouse, a major European producer of titania pigments, having shelved plans early in the year for expansion of its sulfate-process plant at LeHavre, was restudying the matter in September. Present capacity at LeHavre is 91,500 short tons per year. At Calais, Tioxide, associated with British Titan Ltd., completed its expansion to 66,000 tons per year, also by the sulfate process.

Table 11.—Titanium: World production of concentrates (ilmenite and rutile), by country

(Short tons)

Country[1]	1970	1971	1972[p]
Ilmenite:			
Australia	[r][2] 988,820	[2] 914,116	781,324

India[e]	[r] 2,400	3,200	3,400
Sierra Leone	48,593	13,153	--
Sri Lanka[e]	3,100	3,100	3,100
Total	[r] 459,507	423,815	356,853

[e] Estimate. [p] Preliminary. [r] Revised.

[1] In addition to the countries listed, the U.S.S.R. also produces titanium concentrates, but available information is inadequate to make reliable estimates of output levels.

[2] Includes leucoxene.

[3] Production of Comissão Nacional de Energia Nuclear only.

[4] Containing 70–72% TiO_2.

[5] Exports.

[6] Includes a mixed product containing ilmenite, leucoxene, and rutile.

Italy.—Montecatini-Edison, S.p.A., was reported planning to build a facility at Priolo, Sicily, to produce titanium dioxide, titanium sponge, and silica. The company's titanium dioxide plant at Scarlino, its opening delayed since December 1971 pending satisfactory waste disposal arrangements, finally began operations in May. The sulfate wastes were barged to deep water. Late in the year, Società Italiana Resina resumed construction of a 22,000-ton sulfate-process plant to make TiO_2 at Porto Torres, Sardinia. Production is expected by yearend 1973.

Japan.—Production of titanium sponge declined to 5,133 short tons from the 1971 level of 7,470 short tons, a 31% decrease. However, quarterly figures showed a steady increase, and fourth-quarter production was at a 5,800-ton annual rate. Exports of sponge were estimated at a little over 2,000 tons. Titanium slag production decreased to 3,668 tons; after a virtually inactive third quarter, production resumed at an annual rate of 3,250 tons. Ishihara Sangyo Kaisha Ltd., having for 18 months successfully converted ilmenite to rutile, is considering 50% expansion of its plant, bringing it to 45,000-ton capacity. The company is also considering building another pigment plant. Mitsubishi Chemical Corp. is testing another ilmenite-to-rutile process, based on partial chlorination to remove iron, and may erect a 10,000-ton pilot plant on Australia's east coast to process the local off-grade ilmenite.

Norway.—Production of ilmenite concentrates in 1972 was 671,000 tons, a decrease of 5% from 1971 volume.

Sierra Leone.—The Government of Sierra Leone on February 4 entered into an agreement with Sierra Rutile, Ltd., a company owned 60% by Armco Steel Corp. and 40% by Nord Resources Corp. The agreement grants Sierra Rutile exclusive prospecting rights for titanium in the area lately relinquished by Sherbro Minerals, Ltd., and is convertible to a mining lease at the company's request.

South Africa, Republic of.—The Government-owned Industrial Development Corp. announced plans for heavy-sand mining at a large deposit at Richards Bay, Natal. Financial and political difficulties, however, may defer action.

Sri Lanka.—The Asian Development Bank at the close of 1971 approved a $4.15 million loan to Ceylon Mineral Sands Corp., a government-owned company, for expanding and rationalizing its black-sand facilities at Pulmoddai on the northeast coast. Present facilities include mining equipment and a magnetic separation plant at Pulmoddai, where an ilmenite concentrate is made; tailings from this operation are then barged to China Bay, 14 miles down the coast, for recovery of rutile and zircon. Recent fiscal year production has been of the order of 90,000–95,000 tons of ilmenite and 2,100–2,700 tons of rutile; zircon capacity is not yet fully effective. The expansion, with an expected completion date in 1975, will increase annual capacity to 140,000 tons of ilmenite, 12,000 tons of rutile, 8,000 tons of zircon, and a little monazite. The China Bay plant will be moved to Pulmoddai. Feasibility studies of smelting the ilmenite to make titania slag and pig iron are underway.

Taiwan.—The Taiwan Alkali Corp. Ltd., a subsidiary of China Petroleum Corp., announced in July that a plant to produce synthetic rutile from ilmenite was under construction, and that production was expected during the third quarter of 1973. Taiwan Alkali is licensed to use the Benilite process.

Thailand.—Several plants have begun operation during the year to recover byproduct minerals from tin concentration tailings. Ilmenite of pigment grade is among the products, one company reporting an analysis of 53.55% TiO_2, 38.08% FeO, and low chromium.

United Kingdom.—Laporte Industries (Holdings) Ltd. has reported some progress toward effective operation of its 40,000-ton chloride-process titanium dioxide plant at Stallingborough, Lancashire. Full production is reported from the company's two sulfate-process plants, one at Stallingborough, the other at Bunbury, Western Australia.

British Titan, Ltd. (BTP), reported production in excess of nominal capacity at their new 30,000-ton chloride-process titania plant at Greatham. Late in the year, Rio Tinto-Zinc Corp., one of four owners of BTP, reported sale of its 30% interest to the other three partners.

U.S.S.R.—Estimated production of titanium sponge in 1972 was 13,500 short tons, a small increase over 1971 output.

TECHNOLOGY

A materials survey covering geology, mineralogy, extractive metallurgy, and a review of various methods to convert ilmenite to a high-titania product was published.[3] A somewhat similar paper presented in greater detail (1) currently available information on occurrence, reserves, and production of, and demand for, titanium minerals; (2) a discussion of the alteration of ilmenite in nature, and (3) a discussion of the application of thermal reduction, selective chlorination, and selective leaching to the ilmenite-rutile conversion.[4]

A process was described in which iron is smelted out of ilmenite under a sodium borate slag. An acid-soluble but water-insoluble sodium titanate is formed, from which the TiO_2 can be extracted with minimum pollution; the borate is recycled.[5] The Bureau of Mines also was investigating an alternate method of making a high-grade TiO_2 product from ilmenite, in which the concentrate is chlorinated. The iron is separated as a chloride, from which the chlorine is liberated for reuse.[6]

Both rutile and anatase types of pigment have been made available by producers as slurries. A small quantity of a dispersant is added, and 70 tons of pigment in a water suspension is pumped into a 100-ton tank car. One-half hour of air agitation before unloading is sufficient to stir up settled material. Unloading the car takes 45 minutes, storage of the slurry requires less floor space than dry material, and subsequent handling in the plant is far more flexible.

Early in the year Mallinckrodt Chemical Co. took delivery of a 2,700-gallon titanium tank truck, intended for hauling corrosive chemicals.[7] Its advantages over rubber-lined tanks are that (1) it may be used for several different chemicals in sequence with minimum washing between loads, (2) it does not deteriorate nor contaminate the contents, and (3) because of its lighter weight, it can carry 8% more material per unit of dead load.

In June the U.S. Supreme Court refused to review a circuit court decision invalidating the Westinghouse Electric Corp. patent for double-melting of refractory metals.[8] The patent[9] had been successfully challenged by Titanium Metals Corporation of America.

The effect of titanium in blast furnace slags has been reevaluated.[10] Research has determined the ability of the ironmaking process to tolerate titanium oxides up to 10%, and actually to act as a flux up to that point. Unless other adverse conditions arise, these data would seem to point to (1) use of titaniferous magnetites as blast furnace feed, and (2) possible use of Sorel slag as a substitute for fluorspar.

Tungsten

By Richard F. Stevens, Jr.[1]

The domestic tungsten industry recovered significantly in 1972 as production of tungsten concentrate increased 18% to 8.2 million pounds, and concentrate consumption rose 21% to 14.1 million pounds. Imports for consumption of tungsten concentrate rose to a 14 year high and totaled 5.7 million pounds. Concentrate exports in 1972 decreased sharply and totaled slightly less than 0.1 million pounds.

During 1972, the reported price of shipped tungsten concentrate, f.o.b. domestic mines, averaged almost $41 per short ton unit; the quoted European price averaged almost $36 per short ton unit (about $40 per short ton unit with U.S. duty added).

The Government's two-phase tungsten disposal program was continued unchanged during the year at $55 per short ton unit, but only one minor sale was made. Releases which, in previous years, balanced U.S. supply and demand were replaced by less expensive imports.

The low level of European prices reflected the continued decline in foreign industrial activity. Primarily as a result of low tungsten prices, one major European metal trader was forced to declare bankruptcy.

A detailed statistical record of tungsten production, consumption, and trade, by country, was reported quarterly by the United Nations.[2]

Legislation and Government Programs.—Although the General Services Administration (GSA) continued its stockpile disposal programs during the year, only 3,457 pounds of tungsten, in subspecification material, was sold. Under PMDS-ORES-124, excess tungsten concentrate was offered for

sale, for domestic consumption only, at a "shelf" price of $55 per short ton unit adjusted for premiums and penalties. Excess tungsten concentrate, for export, was offered for sale on a monthly sealed-bid basis under PMDS-ORES-123. No concentrate was sold during the year under this program.

H.R. 1257, a bill to temporarily suspend the import duty on tungsten concentrate and on other materials in chief value of tungsten, primarily synthetic scheelite, was introduced before the 93rd Congress on January 3, 1973, and referred to the Committee on Ways and Means.

The first report by the Secretary of the Interior made under the Mining and Minerals Policy Act of 1970 (Public Law 91–631) was released during the year and evaluated the domestic tungsten market.[3] The independent National Commission on Materials Policy, which was formed by Public Law 91-512 on October 26, 1970, to update the 1952 report of the President's Materials Policy Commission, the Paley Commission, and review the Government's policy on materials, issued two interim reports.[4] The Commission's final report, with its findings and recommendations, will be submitted to the President and to the Congress no later than June 30, 1973.

[1] Includes 760,812 pounds of tungsten concentrate sold but unshipped.
[2] Includes 3,304,606 pounds of nonstockpile grade material credited to the concentrate objective.
[3] Includes 174,433 pounds of nonstockpile grade material credited to the concentrate objective.
[4] Includes 79,931 pounds of nonstockpile grade hydrogen reduced metal powder credited to the subobjective.

DOMESTIC PRODUCTION

Although domestic mine production increased 18% to almost 8.2 million pounds of tungsten during the year, mine shipments increased only 3% and totaled 7.0 million pounds. Much tungsten concentrate was stockpiled as producers awaited the development of higher prices. Although 37 mines in nine Western States reported production and 36 mines reported concentrate shipments, only two mines operated continuously throughout the year: The Pine Creek mine and mill of the Mining and Metals Division, Union Carbide Corp., near Bishop, Calif.; and the Climax mine and mill of Climax Molybdenum Co., a division of American Metal Climax, Inc. (AMAX), at Climax, Colo. At Pine Creek, tungsten was the primary mineral value recovered along with minor amounts of molybdenum, copper, silver, gold, lead, and zinc. The average grade of scheelite ore recovered by Union Carbide during the year decreased to about 0.6% WO_3 although production increased 26% and shipments rose 11%. This material was processed on a "straight through" basis and produced ammonium paratungstate (APT), an intermediate processed form of tungsten suitable for ready conversion to high-purity hydrogen-reduced tungsten metal powder.

At Climax, the major mineral value recovered was molybdenum. Concentrates of tungsten, tin, pyrite, and monazite were recovered as byproducts and were entirely dependent upon the rate of molybdenum production. Tungsten concentrate production increased about 11%, although mine shipments were essentially unchanged in 1972. The underground operations and reserves at Climax will be expanded by almost 40% with the addition of surface mining operations that will be phased in gradually as demand warrants. Initial production from the expanded operations is planned for 1974. The byproduct recovery circuit at Climax is being modified to upgrade tungsten recovery operations.[5] A new Reichert Cone separator will operate as a specific gravity-size separator, replacing the older spiral units. A review and description, including flowsheets, of the processing facilities at Climax includes an evaluation of the byproducts plant.[6]

The Tungsten Queen mine and mill of Ranchers Exploration and Development Corp. near Townsville, N.C., remained closed and on standby status throughout 1972.[7] The huebnerite ore of the deposit reportedly has an average content of less than 0.5% WO_3 and ore reserves have been estimated at about 1 million tons.

During the year, Rawhide Mining Co. produced substantial amounts of tungsten concentrate near Rawhide, Nev. from scheelite ore, which averaged about 1% WO_3. All production was sold to Kennametal Inc.

Additional tungsten concentrate production and/or shipments were also reported from Pima County, Ariz.; Inyo, San Bernardino, Tulare, and Tuolumne Counties, Calif.; Boulder and Lake Counties, Colo.; Custer and Valley Counties, Idaho; Deer Lodge and Granite Counties, Montana; Churchill, Elko, Esmeralda, Mineral, Nye, Pershing, and White Pine Counties, Nev.; Baker County, Oreg.; Tooele County, Utah; and Stevens County, Wash.

Under a preliminary agreement, General Electric Co. (GE), will purchase the tungsten properties, mill, and refinery of Minerals Engineering Co. (ME), near Dillon, Mont. Under the agreement, GE will cancel nearly $2 million in notes and interest owed to it by ME, pay $125,000 in cash to the Denver-based firm, and provide royalty payments on future production of up to $1.4 million. The sale will eliminate all of ME's indebtedness to GE and will retire most of the company's remaining short- and long-term debts. Under the agreement, ME will receive a 5% royalty on all production in excess of 200,000 short ton units of WO_3 (almost 3.2 million pounds of contained tungsten) from the Dillon properties.

Although exploration programs conducted by ME since mid-1971 have increased the tungsten ore resources in Montana, a recently completed study indicated that substantial additional expenditures would be required to find and develop additional reserves (material commercially recoverable at current prices).

As part of its program to locate and develop additional tungsten ore reserves in Western States, ME acquired two new scheelite tungsten properties. One of these deposits is the Searchlight property in the Bald Mountain district, White Pine County, Nev. The second, in the Ophir mining district near Avron, Mont., has previously reported intermittent scheelite production from two small open pit mines.

ME took an option on a promising tungsten discovery north of Round Mountain, Nev., in an area where no production or exploration had been previously conducted. Substantial sections of this scheelite mineralization averaged between 2% and 3% WO_3 and were apparently free of molybdenum, pyrite, or other contaminants. To make a more detailed evaluation, ME will build an access road and make bulldozer cuts to expose the mineralized zone for further sampling. Current data indicate that this property should be suitable for open pit mining operations.

[6] Engineering and Mining Journal. Molybdenum—The Firm Base for AMAX Diversification. V. 173, No. 9, September 1972, pp. 104–112.

[7] Ranchers Exploration and Development Corp. Annual Report 1972, 24 pp.

Small quantities of high-grade scheelite ore were produced from the Star Dust claims on Dutch Mountain, near Gold Hill, Utah. The sorted high-grade ore was concentrated to more than 65% WO_3 and sold to Kennametal Inc. at Fallon, Nev. The Fraction Lode property in the same district near the Utah-Nevada border produced mill-grade ore that was concentrated in a gravity separation plant at Redding Spring, 15 miles south of Gold Hill. The WO_3 content of the crude ore was believed to average about 1.5%.

During the year, Transcon Corp. began development of a mine in Elko County, Nev. and recovered low-grade concentrate containing 29% WO_3 from scheelite ores having an average grade of about 0.55% WO_3. Transcon produced and shipped 1,000 short ton units (15,862 pounds of contained tungsten) to the account of Teledyne Wah Chang Huntsville, Huntsville, Ala. This material was upgraded to APT under a toll conversion contract before being further processed at Huntsville. When full-scale production is achieved in 1973, Transcon expects to be capable of producing at a rate of about 250 tons per day. Transcon also indicated plans to upgrade its mill facility in the future to produce concentrates containing 25% to 45% WO_3.

Table 3.—Tungsten concentrate shipped from mines in the United States

Year	Quantity			Reported value f.o.b. mines[1]		
	Short tons 60% WO_3 basis[2]	Short ton units WO_3[3]	Tungsten content (thousand pounds)	Total (thousands)	Average per unit of WO_3	Average per pound of tungsten
1968	9,501	570,040	9,042	$20,293	$35.60	$2.24
1969	8,312	498,706	7,910	18,770	37.64	2.37
1970	9,785	587,088	9,312	23,790	40.52	2.55
1971	7,173	430,427	6,827	20,184	46.89	2.96
1972	7,401	444,145	7,045	18,104	40.77	2.56

[1] Values apply to finished concentrate and ore in some instances f.o.b. custom mill.
[2] A short ton of 60% tungsten trioxide (WO_3) contains 951.72 pounds of tungsten.
[3] A short ton unit equals 20 pounds of tungsten trioxide (WO_3) and contains 15.862 pounds of tungsten.

CONSUMPTION AND USES

Table 5 lists the major domestic companies that were engaged in tungsten processing during 1972 and that reported consumption of over 0.6 million pounds of tungsten annually.

The use of tungsten in cutting and wear-resistant materials, primarily as tungsten carbide, continued to represent the major end use form of tungsten consumption and accounted for 50% of total tungsten product consumption which rose 19% to 13.3 million pounds of tungsten in 1972. The other major end use categories were: Mill products (19%), specialty tool steels (11%), and welding and hardfacing materials (9%). The consumption of intermediate tungsten products used to make end use items during the year was: Tungsten carbide (including cemented, crushed, and cast), 41%; tungsten metal powder (including carbon- and hydrogen-reduced), 39%; chemicals, scheelite (for direct reduction to steel melts), and scrap, 11%; and ferrotungsten, 9%.

The consumption of purchased scrap, as reported to the Bureau of Mines, increased 5.7% in 1972 to about 615,000 pounds of contained tungsten compared with almost 582,000 pounds reported in 1971. Most of this scrap continued to be used in the consumption of cutting and wear resistant materials, welding rods and hard-facing materials, and superalloys.

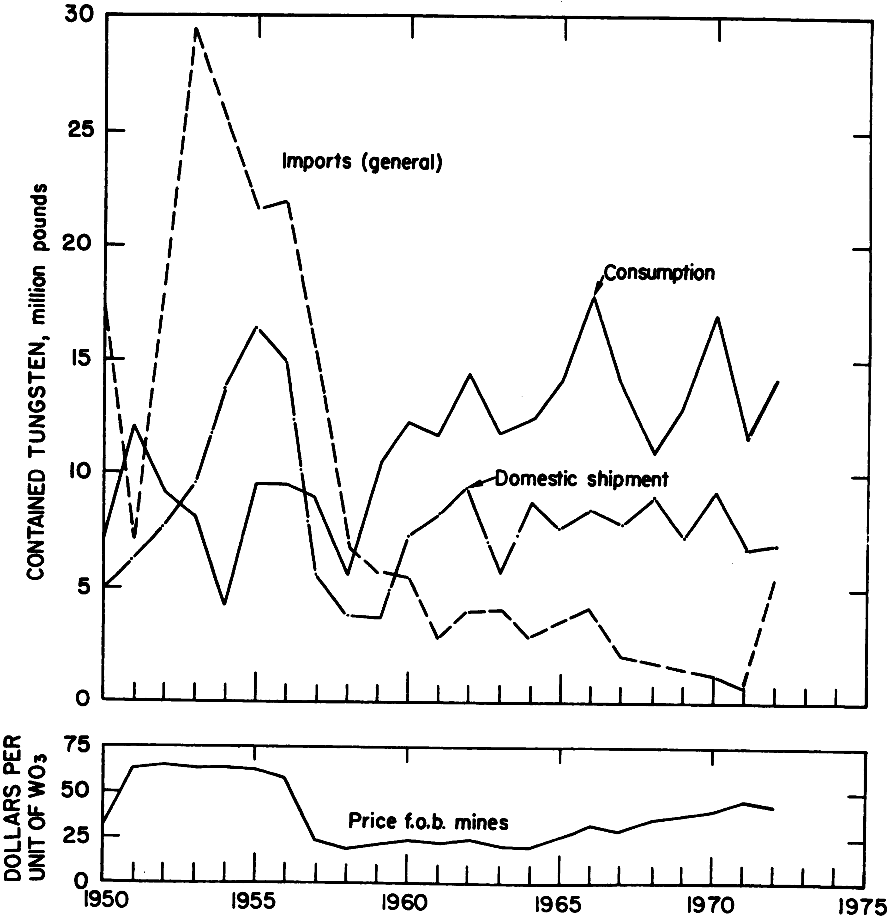

Figure 1.—Domestic shipments, imports, consumption, and average price of tungsten ore and concentrate.

Several special articles and reviews were published that evaluated tungsten supply-demand and consumption patterns, especially in metalworking and cutting applications.[8]

A comprehensive survey of world tungsten production and consumption based upon projected future demand and prices was conducted.[9] The study indicated the difficulty in obtaining complete information on international trade of tungsten concentrate and tungsten products.

Based upon a study conducted for GSA, a detailed analysis of the economics of the tungsten industry was made that evaluated the tungsten supply-demand relationship.[10] A portion of this report evaluated second-

[3] Major consumers of concentrate and APT.

ary (scrap) tungsten supply and estimated that about 2 million pounds of tungsten are recovered annually from new and old scrap.

In October GE sold its refractory metal sheet rolling facility at Euclid, Ohio, to the Specialty Metals Division of AMAX.[11] The plant capacity to make close-tolerance rolled sheet and foil of high-temperature specialty metals was expanded.

Several studies conducted during the year evaluated the application of tungsten carbide in metalcutting uses.[12] These studies reflected the increased interest in tungsten carbide and tungsten carbide-base cutting materials reported statistically.

Mallory Composite Inc. was formed during the year by P.R. Mallory & Co. and

[1] Includes melting base self-reducing tungsten.

[2] Includes both carbon-reduced and hydrogen-reduced tungsten metal powder.

[3] Includes tungsten chemicals, natural and synthetic scheelite, tungsten scrap, and other.

[4] Includes welding and hard-facing rods and materials and nonferrous alloys.

[5] Data may not add to totals shown because of independent rounding.

Composite Sciences, Inc., to market a flexible, cloth-like, wear-resistant coating of tungsten carbide under the name Formaflex.

Metco 72F-NS, a new tungsten carbide coating produced by plasma flame spraying, was developed by Metco Inc. and was reported to have doubled the operating life of other carbide coatings.

GE's Specialty Materials Dept. developed a new cutting material, designated Borazon CBN, in which synthetic cubic boron nitride material is sintered onto a cemented tungsten carbide base.[13]

Fansteel Inc., a leading producer of refractory metals including tungsten powder, tungsten alloys, and tungsten carbides, announced plans to build and operate a new research and development center, in cooperation with the University of Utah at Salt Lake City.[14] The center, which is scheduled to open in the fall of 1973, will conduct company-funded programs on new products and processes. Some areas of investigation are expected to include chemical vapor deposition (CVD), grain growth, oxidation of metals and carbides, and synthesis of silicon carbide.

PRICES AND SPECIFICATIONS

Throughout 1972 the domestic price of tungsten ore and concentrate continued to be quoted at $55 (nominal) per short ton unit, which reflected the GSA shelf price established for the Government's tungsten disposal program. As quoted in Metals Week and in the Metal Bulletin, the London price of tungsten concentrate shown in table 7, fell to a low of £14.00 per metric ton unit (about $30 per short ton unit depending upon the prevailing rate of exchange) during the year. The highest European quotation was reported at £17.50 per metric ton unit ($41.37 per short ton unit) in January.

---

[13] Specialty Materials Dept., General Electric Co. Borazon CBN (Cubic Boron Nitride)—Information Manual. Worthington, Ohio, 1972, 250 pp.

[14] Fansteel Inc. Annual Report 1972. 16 pp.

The price of metallurgical-grade APT delivered to contract customers ranged from about $52 to $55 per short ton unit throughout 1972. A relatively small amount of special material (catalytic-grade APT and "Blue Oxide") was sold for about $57 to $59 per short ton unit. A conversion fee of about $11 per short ton unit was charged for toll processing tungsten concentrate to APT at a recovery of about 96%.

The quoted prices of both carbon- and hydrogen-reduced tungsten metal powder, f.o.b. shipping point, were unchanged during the year. Carbon-reduced tungsten metal powder (98.8% purity in 1,000-pound lots) was quoted by Metals Week at $4.50 per pound of contained tungsten. Hydrogen-reduced tungsten metal powder (99.99% purity) was quoted at $5.43 to $6.94 per pound of tungsten. Within this range, the price of tungsten was dependent upon the powder particle size, or Fisher number.

The quoted price of ferrotungsten in lots of 5,000 pounds or more, ¼-inch lump, packed, f.o.b. destination, continental United States, 70% to 80% tungsten, remained unchanged at $4.60 per pound of tungsten during the year. The quoted price of UCAR, the special high-purity ferrotungsten produced by Union Carbide Corp., was also unchanged during the year at $4.00 per pound of tungsten. During 1972, the U.S. dealer price of ferrotungsten was quoted in Metals Week at $4.50 (nominal) per pound of tungsten.

The price of scheelite concentrate for direct addition to steel melts, although not quoted, was believed to range from about $28 to $44 per short ton unit.

FOREIGN TRADE

Exports.—Exports of tungsten concentrate decreased by a factor of almost 21 to 95,000 pounds, estimated tungsten content, during 1972. Exports of ferrotungsten decreased 82%, and exports of APT increased 66% during the year. Effective January 1, 1972, export data on tungsten carbide powder, which previously had been in a "basket" category, was reported separately and is tabulated in table 11. Because official tungsten carbide export statistics are reported in gross weight, the estimated tungsten content was obtained by multiplying the gross weight by a factor of 0.78, which assumes that the contained weight of tungsten in mixed tungsten carbides averages 78%. There were no reexports of tungsten concentrate or other tungsten products, except APT, during the year. The reexports of APT totaled 84,700 pounds, gross weight, valued at $143,990 and were shipped entirely to West Germany.

Exports of unwrought tungsten metal and alloys in crude form, waste, and scrap in 1972 decreased 70% to 399,443 pounds, gross weight, valued at $539,389, and were shipped primarily to West Germany (72%), the Netherlands (7%), Canada and the United Kingdom (5% each), the Republic of South Africa (4%), and Switzerland and Sweden (2% each). Tungsten and tungsten alloy powder exports fell 19% during the year to 263,383 pounds, gross weight, valued at $1,205,139. This material was exported primarily to Belgium-Luxembourg (34%), Canada (20%), Austria (14%), Japan (8%), Finland and West Germany (5% each), and Sweden (3%).

Tungsten and tungsten alloy wire exports in 1972 increased almost 19% to 141,780 pounds, gross weight, valued at $3,014,806, and were shipped primarily to West Germany (22%), Canada (13%), Belgium (12%), the United Kingdom (11%), Japan (10%), Brazil (7%), Mexico (6%), and Sweden and Singapore (5% each). Exports of wrought tungsten and tungsten alloys increased 26% to 88,812 pounds, gross weight, valued at $1,356,071. Most of this material was shipped to West

Imports.—Imports for consumption of tungsten concentrate during 1972 increased by a factor of almost 14 to a 14-year high of 5.7 million pounds of contained tungsten.

During the year imports of tungsten carbide, from West Germany (74%), Canada (14%), and Sweden (12%), increased 94% and totaled 256,473 pounds of contained tungsten valued at $1,415,814. Imports of waste and scrap containing over 50% tungsten increased by a factor of over 8 and totaled 121,964 pounds of tungsten valued at $342,009. This material was received primarily from the Netherlands (33%), Japan (21%), West Germany (18%), Canada (12%), and France (11%). Imports of unwrought tungsten (except alloys) in lump, grain, and powder rose 42% to 141,390 pounds of contained tungsten valued at $577,114 and were obtained from West Germany (92%), the United Kingdom (5%), and Sweden (3%). Imports of unwrought tungsten, n.e.c. (not elsewhere classified), which totaled 39,264 pounds, gross weight, valued at $133,269, were received from West Germany (76%) and the United Kingdom (24%). Wrought tungsten imports during the year totaled 5,515 pounds, gross weight, valued at $386,781. This material was imported primarily from the Netherlands and Japan (32% each), and Austria (25%).

In 1972, imports of tungsten material classified as "metal-bearing materials in chief value of tungsten," all from the Republic of Korea, increased by a factor of almost three and totaled 100,884 pounds of contained tungsten valued at $179,911. The material imported under this classification was believed to be synthetic scheelite having an average grade of 70% WO_3. Ferrotungsten imports increased by a factor of over 27 during the year to 800,000 pounds tungsten content, and were received primarily from the United Kingdom (42%), Canada (23%), Portugal (13%), and West Germany (11%).

Imports of calcium tungstate, almost all from West Germany, increased by 79% and totaled 27,296 pounds of contained tungsten valued at $272,186. Imports classified as "mixtures to two or more inorganic compounds in chief value tungsten" fell

629.2600	Waste and scrap containing by weight over 50% tungsten.	10.5% ad valorem	50% ad valorem.
629.2800	Unwrought tungsten, except alloys in lump, grain and powder.	21¢ per pound on tungsten content and 12.5% ad valorem.	60¢ per pound on tungsten content and 50% ad valorem.
629.2900	Unwrought tungsten, ingots and shot	10.5% ad valorem	50% ad valorem.
629.3000	Unwrought tungsten, n.e.c	12.5% ad valorem	60% ad valorem.
629.3200	Tungsten alloys, unwrought, containing by weight not over 50% tungsten.	21¢ per pound on tungsten content and 6% ad valorem.	60¢ per pound on tungsten content and 25% ad valorem.
629.3300	Tungsten alloys, unwrought, containing by weight over 50% tungsten.	12.5% ad valorem	60% ad valorem.
629.3500	Wrought tungsten	do	Do.
416.4000	Tungstic acid	21¢ per pound on tungsten content and 10% ad valorem.	60¢ per pound on tungsten content and 40% ad valorem.
417.4000	Ammonium tungstate	do	Do.
418.3000	Calcium tungstate	do	Do.
420.3200	Potassium tungstate	do	Do.
421.5600	Sodium tungstate	do	Do.
422.4000	Tungsten carbide	21¢ per pound on tungsten content and 12.5% ad valorem.	60¢ per pound on tungsten content and 50% ad valorem.
422.4200	Other tungsten compounds	21¢ per pound on tungsten content and 10% ad valorem.	60¢ per pound on tungsten content and 40% ad valorem.
423.9200	Mixtures of two or more inorganic compounds in chief value tungsten.	do	Do.

23% to 28,669 pounds, tungsten content valued at $187,070 from Canada (65%) and West Germany (35%). Under the classification "other tungsten compounds, n.e.c.," 13,425 pounds, contained tungsten, were imported primarily from Canada (86%) and West Germany (12%). There were no reported imports of tungstic acid, ammonium tungstate, or potassium tungstate during the year.

The U.S. import duty on tungsten concentrate (table 16) on material from non-Communist countries was $3.97 per short ton unit while the duty applicable to material from Communist countries was $7.92 per short ton unit. To promote U.S. trade between the U.S.S.R. and the People's Republic of China consideration reportedly was given to providing these two Communist countries "most favored nation" status.

WORLD REVIEW

The Working Group, a subsidiary of the Committee on Tungsten of the United Nations Conference on Trade and Development (UNCTAD), met in Geneva, Switzerland, during June to discuss methods of stabilizing the low world price, obtaining more detailed ore reserve data, and evaluating statistical data on tungsten trade and product consumption. The People's Republic of China, which had been admitted to the UN in 1971, was invited to attend the meeting of the Working Group as an observer. The Committee staff continued to canvass, tabulate, and report tungsten statistics in the quarterly bulletin Tungsten Statistics.

[1] In addition the following countries may consume tungsten concentrate but specific data are not available: Denmark, Finland, Israel, Norway, Switzerland, and Yugoslavia.

[2] Production plus imports minus exports.

[3] Estimated by author of chapter.

Primary source: UNCTAD Committee on Tungsten and Annual Company Reports.

Australia.—About 70% of the country's tungsten production was supplied by King Island Scheelite Ltd., a subsidiary of Peko-Wallsend Ltd. During the year, almost 4 million short tons of overburden and ore material were mined by open pit operations. The 319,600 tons of recovered ore had an average grade of 0.63% WO_3 and was treated to produce 148,920 short ton units of WO_3.[15]

The 3,668,000 tons of overburden removed from the tungsten operations on King Island during the year were used to complete the breakwater and new harbor near the company town of Grassy.

An evaluation of the open pit tungsten reserves indicated a mine life of about 5 years under current mining and milling practices. Future underground operations are expected to be conducted to recover scheelite from the deposit, which extends under the sea.

King Island's expansion program, which was to have doubled production within 3 years, was discontinued due to depressed world prices. However, the development of underground mining operations was continued during the year.

Tungsten concentrate was produced from wolfram ore recovered from underground operations at Rossarden in northeastern Tasmania by Aberfoyle Ltd.[16] Tungsten was also recovered from the mine of Storeys Creek Tin Mining Co. N.L., a tungsten-tin producer owned entirely by Aberfoyle. Late in 1971 the mill at the Storeys

Creek mine was closed down, and all ore in 1972 was sent to the nearby Aberfoyle mill for treatment and concentrating.

At Wolfram Camp, Queensland, tungsten concentrate was recovered from wolfram ores by Metals Exploration N.L. Scheelite ore, recovered by Mareeba Mining and Exploration Pty Ltd. at its Mount White lease, was concentrated at the Irvinebank custom mill. R.B. Mining Pty Ltd. reopened a number of old shafts and installed rail tracks to provide transportation by ore cars.

Bolivia.—Empresa Nacional de Fundiciones (ENAF), the Bolivian national smelting company, and the Czechoslovakian firm Skoda Export signed an agreement whereby Skoda will conduct a feasibility study of installing a ferroalloy plant near Lake Titicaca. It is anticipated that the plant would produce about 550 tons of ferrotungsten (about 0.9 million pounds of contained tungsten) annually.

After visiting the major Bolivian tin-tungsten mines, the privately owned Chojilla mine, and the state-owned Bolsa Negra and Kami mines, Skoda's technicians estimated that Bolivian tungsten reserves were sufficient to last for about 50 years.

Brazil.—A cost evaluation study of the major tungsten deposits in Northeast Brazil was published.[17] Of the some 250 to 300 scheelite-bearing deposits located in central and western Rio Grande do Norte, northern Paríba, and eastern Ceará, most of the Brazilian production comes from four underground mines. The largest producer, the Brejuí mine, upgrades 300 tons of ore per day containing 0.70% WO_3 to commercial-grade concentrate averaging 70% WO_3. The overall recovery of the Brejuí mill averages 80% and supplies about 57% of the country's production.

The Barra Verde mine and mill supplies about 26% of Brazilian tungsten production from scarn-scheelite ores, which are recovered from deep deposits and processed at a rate of 100 tons per day to 70% WO_3 concentrate. The Cafuca and Bodo mines recover tungsten from narrow, high-grade ore deposits containing from 1% to 2% WO_3 and process the ores at rates between 25 and 50 tons per day. The remaining deposits are primarily intermittently worked open pit operations. Concentration is done by hand crushing, screening, and jigging. The recovery of scheelite by primitive hand concentration methods is not greater than 40%.

Approximately 80% of the Brazilian production is exported to the United Kingdom, West Germany, Austria, France, Belgium-Luxembourg, Sweden, and Japan. The remaining 20% is consumed almost entirely in the Brazilian steel industry.

Canada.—Although continuous high-quality scheelite operations were maintained throughout the year by Canada Tungsten Mining Corp. Ltd. (CTMC), the country's major tungsten producer, at Tungsten, Northwest Territories, 1972 production fell about 3.5%. Mine production, all from open pit operations, totaled 158,706 short ton units of WO_3 (2.5 million pounds of contained tungsten), and the concentrator operated at 92.53% of possible time treating an average of 472 short tons per day.[18] Overall mill recovery of WO_3 averaged 79.83% during the year. The newly mined ore had a higher chert content and caused additional metallurgical processing problems. Mill circuit modifications alleviated most of the problems caused by the chert material. The average grade of ore processed decreased slightly and was 1.15% WO_3 in 1972, compared with an average grade of 1.19% WO_3 in 1971.

In addition to the scheelite concentrate, 225,125 pounds of byproduct copper in concentrate was produced during the year, a decrease of 7% compared with that of 1971.

At yearend CTMC estimated its reserves of scarn-type ore in place at about 240,000 tons averaging 1.65% WO_3. In addition, 157,600 tons of scheelite ore averaging 1.06% WO_3 was stockpiled. The reserves and the stockpile material contain approximately 8.9 million pounds of tungsten, which, if all was recovered, would be sufficient to sustain 3 to 4 years production at the current rate.

An accelerated deep drilling exploration program completed in the 1972 season outlined a new mineralized zone of tungsten ore. The ore body was of sufficient importance to warrant driving an adit for about 4,000 feet. Upon completion, an evaluation will be made of the feasibility of conducting underground mining operations, which might allow mining to be conducted on a year-round basis. The open pit mining season is restricted by the severe climate to about 5 months per year, primarily during the summer. If underground mining operations are to be conducted, it is anticipated that additional milling facilities will be required.

---

[17] Barbosa, Frederico L. M. Financial Analysis of Tungsten Deposits in Northeast Brazil. M. S. Thesis (T 1411), Colorado School of Mines, Golden, Colo., 1972, 83 pp.

[18] Canada Tungsten Mining Corp. Ltd. (Toronto, Canada). Annual Report 1972. 9 pp.

During the 1972 mining season, a total of 203,551 tons of ore containing an average of 1.05% WO_3 was mined, crushed, and stockpiled. In addition, 297,240 tons of waste was removed from the pit area. The main changes in mining practices developed during the year were improved methods of stockpiling and of blending tungsten concentrate.

CTMC's Vancouver Leach Plant in North Vancouver, British Columbia, continued to operate continuously throughout the year on a 5-day-per-week schedule to upgrade scheelite concentrate received from the mine and mill. Overall recovery of the leach plant remained good and averaged 97.1% in 1972, a slight decrease from the 98% recovery reported in 1971.

During the year, the Canex Tungsten Division of Placer Development Ltd. continued to recover tungsten from its Invincible scheelite property at Salmo, near Trail, British Columbia. The Canex mill treated a total of 198,000 tons of ore averaging 0.58% WO_3 at an average rate of 529 tons per day with a recovery of 81.5%.[19] Approximately one-fifth of this material was recovered as a high-grade table concentrate. In 1972, the average price received for tungsten concentrate fell to $34.05 per short ton unit of WO_3, f.o.b. Vancouver. As a result of reduced sales, mill stocks more than doubled and totaled 53,275 units (0.85 million pounds of contained tungsten).

Yearend reserves of broken and unbroken scheelite ore at Salmo totaled 104,000 tons at an average grade of 0.55% WO_3. It is expected that this reserve will be depleted by mid-1973 at which time the operation will be terminated.

China, People's Republic of.—Analyses of the People's Republic of China (PRC) export statistics, as reported by its trading partners, indicated that exports of tungsten concentrate decreased because the PRC was producing less and consuming more concentrate in the country's growing steel industry. There was no indication that the PRC was stockpiling tungsten concentrate in significant quantities. It is believed that most of the easily located rich surface deposits have been depleted. Future production will be supplied primarily from low-grade tungsten ore recovered from deep underground operations. Domestic consumption is expected to continue to increase and may be approaching 5.7 million pounds of contained tungsten annually to meet the rising needs for cutting tools, drill bits, and specialty tool steels.[20] The PRC will probably not resume previous high levels of tungsten production during the 1970's.

Tungsten mining requires a continuous influx of capital to maintain a stable production level because operators must be constantly moving on to new ore pockets. Since the early 1960's improvements and expansions reported at tungsten mines and mill sites have been neglegible and have resulted in decreasing levels of production in the PRC.

Although tungsten mining and ore dressing in the PRC are generally primitive the major mines in Kiangsi and Kwangtung provinces reportedly recover tungsten from wolframite ores by mechanized techniques. Large scheelite deposits have been discovered in Hunan Province.

Exports of tungsten concentrate to the U.S.S.R. from PRC which decreased substantially from about 21,000 tons (gross wt.) in 1960 to zero in 1968, were resumed in 1970 and had increased by a factor of almost 7 in 1972 as indicated below:

Year	Shipments of tungsten concentrate from PRC to U.S.S.R.	
	Gross weight (tons)	Estimated tungsten content [1] (1,000 lb.)
1972 [p]	5,786	6,248
1971	5,282	5,699
1970	881	951
1969	0	0
1968	0	0

[p] Preliminary.

[1] Assumed 68% WO_3 content; conversion factor: $=0.68 \times 0.7931 \times 2000 = 1079$ lb. W (est.)/st (gross wt.).

---

[19] Placer Development Ltd. (Vancouver). Annual Report 1972. 32 pp.

[20] Canadian Min. J. Tungsten. V. 94, No. 1, January 1973, p. 24.

France.—During the year Sté. Minière d'Anglade processed tungsten ore having an average content of 1.39% WO_3 at its mill adjacent to the Salau (Ariège) ore body. Mill production in 1971 was of two different grades: 75% WO_3 concentrate and 30% WO_3 semiconcentrate. Additional mill facilities were installed in 1972 in an attempt to upgrade the WO_3 content of the semiconcentrates and increase production. Sté. Minière et Métallurgique du Chatelet produced tungsten concentrate at its Enguiales exploitation in Aveyron.

Korea, Republic of.—Because the Republic of Korea has historically been a major producer of tungsten concentrate, the country has indicated interest in establishing concentrate processing facilities and in the development of a domestic tungsten carbide cutting tool industry.

The Sangdong mine of Korea Tungsten Mining Co., Ltd., (KTMC) which is 15.5% Government owned, continued to be the country's major tungsten producer in 1972 and accounted for over 88% of the domestic supply as shown in the following tabulation:[21]

Company	Short tons (gross weight)
Bando Mining Co., Ltd	10
Kaya Ind. Co., Ltd	56
Korea Tungsten Mining Co., Ltd.	
Dalsong mine	63
Sangdong mine	3,568
Okbang Mining Co., Ltd	314
Ssangjon Mine	10
Wolak Mining Co., Ltd	6
Other companies (10 mines)	7
Total	4,034

A plant for processing tungsten concentrate to APT was completed by KTMC in December adjacent to its Sangdong mine and mill. When in full-scale operation, this plant is expected to have capacity for processing about 100,000 short ton units of WO_3 (almost 1.6 million pounds of tungsten per year).

Malaysia.—There was a substantial increase by a factor of almost 16 in the recovery of tungsten concentrate from West Malaysia tin tailings.[22] Beh Minerals, the leading company in this field, has added tungsten and other heavy mineral extraction mechanisms on line at the end of its tin processing shed.

Portugal.—Preliminary reports indicated that tungsten production increased by about 3% during 1972. Because of the depressed market prices and the lower grade of ore mined, it was uneconomical for the major producer, Beralt Tin and Wolfram Ltd., to sell high-grade (74% WO_3) wolframite concentrate recovered from its Panasqueira ore body in central Portugal.[23] The bulk of this material was stockpiled. Proven and inferred tungsten ore reserves at Panasqueira were reportedly sufficient to provide a mine life of about 9 years.

Further consideration was given to the possible establishment of a tungsten processing plant in Portugal, but, because of the depressed tungsten market, it was decided to defer action until a later date.

Production of ferrotungsten containing 82.9% tungsten increased 23% to 370 tons during the year. This material represented over 90% of reported Portuguese tungsten concentrate consumption.

Rhodesia, Southern.—In 1972, Rhodesian tungsten production fell by over 20% and was obtained primarily from the Beardmore mine, operated by the Messina (Transvaal) Development Co., Ltd., in the Victoria district near Bikita.[24] A total of 44,300 short tons of ore grading 0.64% WO_3 was mined at Beardmore and 38,600 tons of ore containing about 0.72% WO_3 was milled during the year. Overall recovery averaged 73.5% and 314 tons of scheelite concentrate containing 209 tons of WO_3 (0.3 million pounds of contained tungsten was produced.

At yearend, the Beardmore ore reserve totaled 35,300 tons averaging 0.64% WO_3. Since exploration programs failed to uncover additional worthwhile tungsten mineralization the mine will be forced to close in the fall of 1973 when present ore reserves are exhausted.

A slime treatment plant was erected adjacent to the Beardmore mine and was scheduled to become operational in February 1973 with a processing capacity of 2,200 tons of low-grade slimes per month. The total capital expenditure which will be incurred in the plant construction was expected to be about $75,000.

[23] Beralt Tin and Wolfram Ltd. (London). Annual Report 1972. 19 pp.
Charter Consolidated Ltd. (London). Annual Report 1972. 51 pp.
———. Annual Report 1973, 50 pp.

[24] The Messina (Transvaal) Development Co., Ltd. Johannesburg, (Republic of South Africa). Annual Report 1972. 28 pp.

Total tungsten production at the Beardmore complex (mine, mill, and slime treatment plant) in 1973 was expected to increase about 3% and total 215 tons of WO_3 contained in 331 tons of concentrate. This material will be recovered by milling 35,300 tons of ore from the Beardmore mine and by processing 20,900 tons of low-grade slimes at the new treatment plant.

South Africa, Republic of.—Hard Metals Ltd., a subsidiary of Anglo American Corp. of South Africa Ltd., was the country's only producer of tungsten carbide from ore.[25] Hard Metals previously imported its tungsten concentrate starting material from South Korea but currently obtains almost all its requirements from African sources. The major supplier, Messina (Transvaal) Development Co., Ltd., provides scheelite concentrate averaging 68% WO_3 from its Beardmore mine in Southern Rhodesia, which borders South Africa.

South-West Africa, Territory of.—The country's major tungsten producer, Brandenburg West, operated by the South West Africa Company Ltd., continued to recover tungsten from mixed tin-tungsten concentrates obtained by open pit mining operations.[26] Although native miners were on strike for about 3 months, the volume of the tin-tungsten concentrate produced during the year increased about 7%. Although the average grade of tungsten concentrate fell 13% to 17.66% WO_3, the average grade of tin concentrate increased slightly to 33.58% tin. Additional mine loading equipment was obtained to expedite overburden removal and facilitate ore handling.[27] Other capital expenditure made was associated with the replacement of the vibrating screen in the jigging circuit of the gravity recovery plant.

At yearend, the ore reserve at Brandenburg West was estimated at about 6.8 million tons having an average grade of 0.153% tin and 0.069% WO_3.

Development and construction of the underground Krantzburg scheelite mine and adjacent mill located about 100 miles northwest of Windhoek were conducted during the year. The mill was designed to treat about 7,500 net tons of ore per month and, when operational, concentrate production (65% WO_3) was expected to total about 50 net tons per month. The ore reserves of this property, which will be operated by Nord Resources Corp., have not been fully determined. Preliminary investigations indicated an ore body sufficient to provide a mine life of 8 to 10 years.

Spain.—A detailed evaluation of the present and projected Spanish mineral industry was conducted by the Office of the Director General of Mines in the Ministry of Industry. Four of the nine tungsten mines in operation during the year provided two-thirds of the Spanish production. Three of the mines, Santa Comba, San Finx, and Monte Neme, are located in the western end of the Province of La Coruna in the northwestern corner of Spain and each produces about 14% of the country's total tungsten output. The major domestic tungsten operation, the Merladet mine and mill, supplys about 25% of the total Spanish production in the form of high-grade scheelite concentrate having a guaranteed content of 75% WO_3 and low impurity levels.[28]

Electrometalúrgia del Agueda of Spain evaluated plans for producing tungsten metal from domestic concentrate by the aluminothermic process.

Sweden.—Evaluations of AB Statsgruvor's newly developed Postman scheelite deposit at Elgfall in central Sweden were conducted during the year and ore was taken a few miles to the company's tungsten mine and ore dressing plant at Yxsjöberg where both a high-grade concentrate, containing about 73% WO_3, and a low-grade semiconcentrate, containing about 35% WO_3, were produced.

Metal Bulletin (London). Scheelite-Highest Quality Merladet Brand. No. 5744, Oct. 24, 1972, p. 43.

Sandvikens Jernverks AB and Fagersta AB both consumed tungsten concentrate (scheelite) in the production of cemented tungsten carbides and specialty steels. Sandviken originally obtained much of its scheelite concentrate from Canada (CTMC).

Thailand.—Production and exports of tungsten concentrate increased substantially and replaced fluorite as the second major Thai mineral foreign exchange earner in 1972.[29] Although difficulties with lawlessness, corruption, poaching, and smuggling continued to plague the mineral industry, preliminary Government forecasts for 1973 were optimistic. An initial report of the West German Geological Mission indicated promising areas of tungsten mineralization in the central and western portions of northern Thailand. About 90% of the country's nine tungsten mines and 179 tin-tungsten mines, located primarily in the southern part of the country, were plagued by illegal diggers on the sites.

U.S.S.R.—A detailed review of byproduct tungsten extractive and processing metallurgy operations at the Tyrhy-Auzsk ore dressing plant in the northern Caucasus was reported.[30] A computer and an automatic sampler are being installed that will continuously record tungsten and impurity contents, will record the main technological indices of the plant operation, and automatically make necessary corrections in operating procedures.

The U.S.S.R. initially announced plans to increase production of tungsten concentrate by 60% during the 9th Five Year Plan, 1971–75. While production in 1971 was believed to have been 4% higher than in 1970, production in 1972 was estimated to have increased about 3%.

When the Primorsky (Maritime) Kray production facility in the Far East is completed it is scheduled to contribute much of the increase in tungsten output planned during 1971–1975. The Vostok (East) Combine, a large mining and concentrating operation located on the western slope of the Sikhote-Alin' mountains in the region near the Iman and Tatibe Rivers has been under construction since 1967. Some tungsten ore was believed to have been trucked to this facility and processed in late 1972. Another significant tungsten deposit has been discovered in the vicinity of Luchegorski close to the Trans-Siberian Railroad right-of-way. The rich ore of this deposit is amenable to open-pit mining and production is scheduled to start in 1974.

Facilities for the recovery of tungsten ore are to be put in operation in 1973 at the Solnechnyy copper concentrator in Khabarovsk Kray to exploit material mined from deposits in the Myao Chan foothills. Near the end of 1972, a mine was under construction near the Balkhash mining and metallurgical complex in Kazakhstan to produce tungsten and coproducts molybdenum and bismuth. Exploitation and development of the Maykhura tungsten deposit in Tadzhikstan is also scheduled to begin during the current 5-year plan. In the Buryat ASSR extensive investigation of the Inkurskiy deposit during 1966–70 permitted work to be started on the development of new mines to support operations at the Dzhida tungsten-molybdenum processing combine which began operation of a new ore dressing facility early in 1972. It was announced in 1972 that plans had been prepared for the reconstruction of the concentrator at Tyrny-Aux which permit an increase in the ore throughput of 3 million tons per year. Plans for the construction of additional mines and concentrating facilities at Ingichka in Uzbekistan were also announced.

To supplement domestic supplies the Soviets have imported tungsten concentrate, primarily from the People's Republic of China which, after cutting off exports to the U.S.S.R. in the mid 1960's, resumed them in 1970.

When the supply of tungsten in the U.S.S.R. was restricted, its use, primarily in the tool steel industry, experienced a dramatic shift in 1967 and subsequent years as molybdenum replaced tungsten in tool steels.[31]

United Kingdom.—Primarily as a result of the low European price of tungsten concentrate that prevailed during the latter part of 1971 and throughout 1972, a major London-based dealer, Metal Traders Ltd., was forced to declare bankruptcy. Between 3,300 and 4,400 tons (about 3.4 to 4.5 million pounds tungsten) of Metal Traders' stock of tungsten concentrate were reportedly purchased by Climax Molybdenum Co. at £14.90 per metric ton unit (about $35.29 per short ton unit). About one-third to one-half of this material was believed to be of Chinese origin. In addition, some tungsten concentrate stocks were reportedly being held by banks until a better price could be obtained.

Zaire, Republic of.—In association with Philipp Brothers, Syndicat Minier de l'Etain (SYMETAIN) is a major wolframite producer located at Kalima and Punia, both in the Maniema district in Kivu.[32] Although official data for 1972 are not yet available, the SYMETAIN tungsten production was estimated to total about 66 tons, gross weight. Cobelmin-Zaire (COBELMIN), a subsidiary of Compagnie Belge d'Entreprises Minieres, recovers almost 60% of the country's tungsten production at two locations in Kivu Province. About one-quarter to one-third of the tungsten output in Zaire is produced in Kivu by KIVUMINES. A promising joint venture with Falconbridge of Canada Ltd. to exploit a wolframite deposit in northern Kivu was abandoned.

TECHNOLOGY

Studies were continued during the year by Bureau of Mines research metallurgists in an attempt to develop an economic process for recovering tungsten from the low-grade brine deposits of Searles Lake, Calif., which contain an estimated 135 million pounds of contained tungsten and could double the Nation's tungsten reserves.

An extensive evaluation of coal-cutter materials, conducted by scientists as part of the Bureau's health and safety program, indicated that tungsten carbide was among the least sparking and least incenditive of the cutting materials tested.[33]

As a result of research studies by Bureau of Mines engineers, methods were developed for the preparation of tungsten carbide from electrolytic solutions.[34]

The high volume of throwaway tool bits used in metal cutting operations prompted the investigation and development of methods to recover tungsten carbide by Bureau metallurgists.[35] Comparitive costs of tungsten carbide made from virgin tungsten powder and that recovered from scrap are roughly 4 to 1. Thus, the processing of scrap material is appealing both to carbide processors and to scrap metal dealers. In addition, it is further reported that the cost of processing scrap by this method is approximately one-fourth that of other reclamation methods.

Several studies conducted by research metallurgists at the Battelle Memorial Institute, Columbus, Ohio, developed economical freeze-drying processes for the production of ultrafine tungsten and tungsten carbide powders.[36] The fine cemented carbide powder produced by these techniques is expected to provide improved life for cutting tools.

A detailed review of chemical vapor deposition (CVD) methods used in tungsten processing techniques was sponsored by the

Materials Science and Technology Division of the American Nuclear Society at the University of Utah in Salt Lake City.[37] Topics covered included fundamentals and techniques of CVD processes, composites, coatings, fibers, and powders; and application.

Continuing studies on vapor-deposited tungsten by National Aeronautics and Space Adminisration (NASA) metallurgists at the Lewis Research Center indicated that mechanical properties could be improved by the selective incorporation of various nonmetallic impurties.[38]

Additional studies of the mechanical behavior of CVD tungsten by University of Utah research metallurgists indicated a lower strength than that of standard powder metallurgy tungsten.[39] A way to fabricate complicated tungsten shapes was developed in which gaseous tungsten hexafluoride and hydrogen react at high temperatures to deposit pure tungsten on a copper pipe or mandrel.[40] When the copper is etched out, a pure tungsten pipe remains.

To eliminate the minute pits and flaws that lower the strength and increase the rate of rejects in cemented tungsten carbide products, Kennametal developed a process for producing exceptionally high-quality cemented tungsten carbide forms by simultaneous application of isostatic pressure of up to 20,000 pounds per square inch, and elevated temperature up to 2,750° F.[41]

In addition to using hot isostatic processing for bonding and pressing tungsten metal powder in variety of applications, several companies have reported using this process to manufacture tungsten carbides and tool steels.[42]

Consolidated tungsten metal was produced in good yields on a small scale by aluminothermic reduction of tungstic oxide with small amounts of calcium and sulfur to initiate the reaction at 450° C.[43] The aluminum in the consolidated tungsten, which initially contained 1,400 parts per million, 0.14%, was subsequently reduced to 30 parts per million by nonconsumable arc melting.

Submicroscopic gas bubbles trapped in doped tungsten filaments impart greater high-temperature strength to the metal by solid solution or dispersed second phase alloying.[44]

Tungsten alloys having excellent tensile strength and stress-rupture properties at 1,650° C and 1,920° C were prepared from sintered powder blends of tungsten and tungsten zirconium or zirconium nitride by high-impact (Dynapak) extrusion.[45] The strengthening was attributed to solid solution strengthening by zirconium and by submicron particles of zirconium dioxide.

A study of the development of submicroscopic porosity in several grades of doped tungsten wire was conducted in the temperature range between 3,000° and 3,350° C.[46] The extremely small submicroscopic pores inhibit recrystallization and permit development of the interlocking grain structure necessary for sag-resistant filaments.

A prototype device was developed for semiautomatic gas tungsten arc welding of small diameter tubing.[47] Because the torch nozzle is always centered over the weld joint where the arc is started, the arc length remains constant and arc initiation is easier since the tungsten is preset for the weld.

Uranium

By Walter C. Woodmansee[1]

The domestic uranium industry, from mining and milling through the nuclear fuel cycle to fuels reprocessing and waste management, made further progress toward establishing facilities adequate for an accelerating future demand. Exploration for uranium in the Western States was at a rate similar to that of 1971, but emphasis was on deeper drilling. Discoveries of significant new ore deposits were announced. There was little change in ore reserves, as determined by the Atomic Energy Commission (AEC), which placed increased emphasis on potential resources and on higher cost ores. Output of U_3O_8 concentrate increased; 20 mills, three of which started production during the year, were in operation. Two mills were closed and placed on a standby basis. Other sectors of the nuclear fuels industry continued development plans, which, however, were slowed by a soft market and environmental opposition. The AEC announced a new program of sharing enrichment technology with selected domestic companies and foreign nations.

Despite plans for an expanding domestic nuclear industry, the current market was one of continuing oversupply, excessive stocks, and soft prices. The AEC announced a new policy whereby it would not sell its U_3O_8 stockpile in the domestic or foreign market but would use it in preproducing enriched uranium for future sales, thereby avoiding direct competition with U_3O_8 producers in the domestic market. Although a uranium surplus prevailed, this situation was considered temporary; it was anticipated that low-cost U_3O_8 reserves and forward supply were not improving at

[3] Based on estimated recoverable content, average AEC price, and estimated average price for private sales for 1968–70; private sales only in 1971–72.

[4] Includes marketable concentrate from leaching operations.

[5] Non-Communist only.

[6] At $8 per pound U_3O_8.

[7] In exploration, mining, and milling, at yearend.

Sources: U.S. Atomic Energy Commission and Federal Bureau of Mines.

---

[1] Physical scientist, Division of Nonferrous Metals, Associate Directorate—Mineral Supply.

a satisfactory rate and that major new investments in exploration and development would be necessary to supply projected demand.

Orders for nuclear powerplants were higher compared with 1971, although delays continued in licensing and construction. The AEC made plans for expediting the licensing procedure by enlarging its regulatory staff and streamlining licensing procedures.[2] During 1972, seven nuclear powerplants were licensed for full-power operation, two for partial power operation, and eight for construction starts.

Nuclear power development plans were prevalent worldwide, particularly (outside the United States) in Western Europe, Japan, and the U.S.S.R. Also, many developing nations had programs for nuclear power. New uranium mines in Australia, Niger, and the Territory of South-West Africa were under development to supply a growing number of international contracts for U_3O_8.

Exploration.—Footage in exploration and development drilling, reported to the AEC by 84 companies, was at a rate similar to that of 1971. The trend continued toward deeper exploration drilling. About 32% of this activity was in areas more than 50 miles from existing production centers. Principal exploration was in Wyoming (43%), New Mexico (23%), and Texas (22%). Salient data for 1972 were as follows: [3]

Land held, yearend	million acres	5.6
Expenditures:		
Land acquisition	million dollars	4.7
Drilling (surface):		
Exploration	do	15.4
Development	do	2.7
Other	do	9.6
Total		32.4

The industry held 17.7 million acres at yearend 1972 (19 million acres in 1971) and planned drilling programs of 18.5 million feet ($35.5 million) in 1973 and 20.3 million feet ($38.2 million) in 1974.

Table 2.—Surface drilling for uranium

Reported significant uranium discoveries during the year included those of Western Nuclear Corp. in the Ruby Wells area, McKinley County, N. Mex., and Atlas Corp. in the Sage Plains, near Moab, Utah.

A joint venture involving Ranchers Exploration and Development Corp., Occidental Minerals Corp., and Frontier Mining Corp. planned a 2-year exploration and development program in northwest New Mexico.

Reserves and Resources.—Domestic uranium reserves at $8 per pound U_3O_8 remained unchanged at yearend 1972, additions being approximately equal to depletion by production during the year. Reserves at $10 per pound U_3O_8 increased by

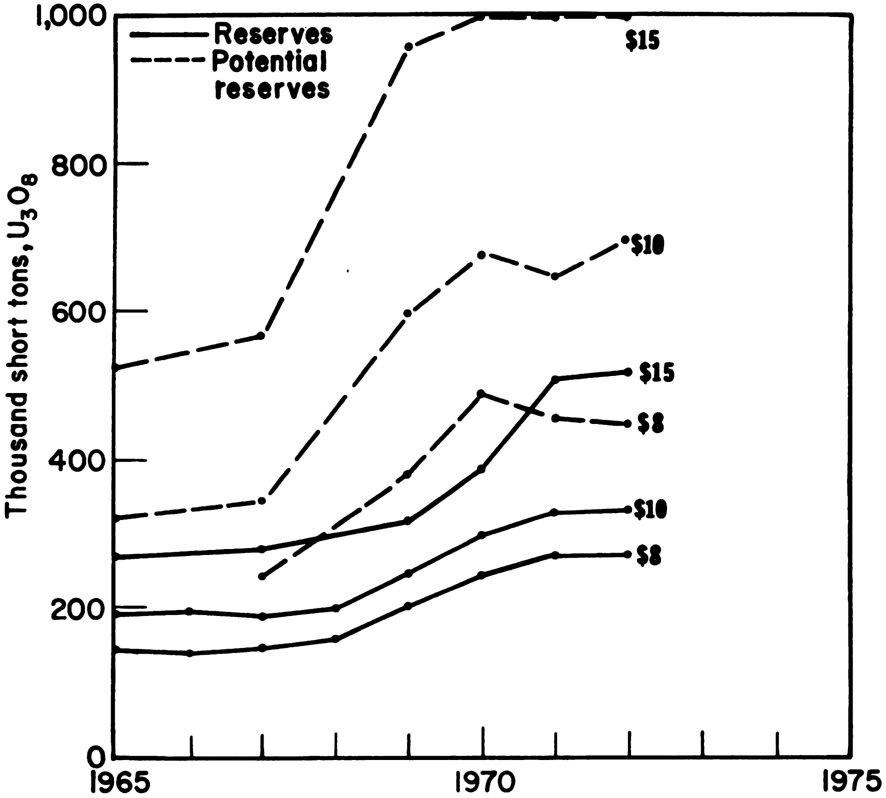

Figure 1.—Domestic uranium resources.

4,000 tons U_3O_8.[4] There were 781 reserve properties in the $8-per-pound category, of which 49% were in New Mexico and 36% in Wyoming.

In 1972, the AEC extended potential resources (those in unexplored areas, mainly in and near known deposits and districts) to include the $15-per-pound cutoff. Reserves and potential resources in this category totaled 1.5 million tons U_3O_8.[5]

DOMESTIC PRODUCTION

Mine.—Uranium mine output showed a significant increase in terms of gross weight of ore, recoverable U_3O_8, and average grade of ore. New Mexico and Wyoming continued as the dominant producing States, accounting for 75% of total output. There were 141 underground (40% of output) and 37 open pit mines (58% of output) producing during the year; in addition to these normal mining operations, 196 tons of U_3O_8 was produced at 12 miscellaneous operations (leaching, mine water, raffinate). Development was underway at a number of properties, particularly in New Mexico, Wyoming, and Utah.

Mill.—Mill production increased by more than 600 tons U_3O_8. Three new mills went onstream during the year, and two mills ceased operations and were placed on standby. Total existing capacity was almost 32,000 tons of ore throughput per day and 19,000 tons U_3O_8 per year. The mills were worked at 68% of capacity.

Nuclear Fuel Materials.—Development of private commercial facilities continued for production of uranium hexafluoride (UF_6), nuclear fuels and fabrication in fuel assemblages, spent fuel reprocessing, and depleted uranium. Approximately 21 companies with 30 plants were active in the nuclear fuels industry or planned new installations. Uranium enrichment was the only service not provided by private industry, but several proposals for enrichment facilities were made to the AEC.

[5] U.S. Atomic Energy Commission, Grand Junction, Colo. Potential Uranium Resources of the Western United States. GJO-104(73), May 1973, 7 pp.

Uranium Hexafluoride.—The UF_6 plant of Allied Chemical Corp. at Metropolis, Ill., was closed down much of the year and, when in operation, worked at only partial capacity. Kerr-McGee Corp. operated its UF_6 plant at Sequoyah, Okla., at 60% of capacity during the year. This idle capacity reflected a shortage of orders for U_3O_8-UF_6 conversion.

The AEC planned to process its U_3O_8 stockpile to UF_6 at its own facilities.

Enriched Uranium.—During 1972, the AEC received revenues of $138 million for

4.3 million Separative Work Units (SWU)[6] of enriched uranium services to domestic (2.4 million SWU) and foreign (1.9 million SWU) customers. Since toll enrichment services began in 1969, cumulative revenues have totaled $523 million. New contracts were negotiated with 16 domestic and 23 foreign customers during the year and, at yearend, 46 domestic and 46 foreign contracts were active, providing for 290 million SWU, which (at $32 per SWU) were valued at $9.3 billion. In addition, during 1972 the AEC received $9 million for in-situ enrichment services, a procedure whereby AEC-owned enriched uranium held under lease may be converted to private ownership.[7]

The AEC's three gaseous-diffusion enrichment plants—at Oak Ridge, Tenn., Paducah, Ky., and Portsmouth, Ohio—were operated at about 40% of capacity (17.2 million SWU), which was sufficient for domestic and foreign orders. It was anticipated that additional enrichment capacity will be needed in the early 1980's and plans were underway to expand annual capacity to 26.5 million SWU and preproduce enriched uranium using the AEC's U_3O_8 stockpile at a higher tails assay. According to plans, the transaction tails assay would be 0.2% U_{235}, whereas the actual operating assay would be 0.275% U_{235} or 0.30% U_{235}. More feedstock would be processed, using the stockpile material, and fewer SWU's would be required, resulting in reduced operating costs. The deferment of the need for new capacity would permit the use of any newly developed technology and may provide greater opportunities for private industry participation in enrichment operations.[8] Preproduced enriched uranium was expected to fill orders in the late 1970's.

---

[6] Measure of work expended in separating a quantity of uranium (in kilograms) at a given assay into two fractions—ore enriched in U_{235} to a specified grade and the other deficient in U_{235} to a specified tailings grade.

[7] U.S. Atomic Energy Commission. 1972 Annual Report to Congress. Operating and Developmental Functions. Jan. 31, 1973, p. 36.

Following AEC announcements providing for possible future access to enrichment technology and encouraging private participation in enrichment operations, a number of proposals were made to the AEC. Early in the year, Reynolds Metals Co. planned to create a consortium for a $2.2 billion, gaseous-diffusion operation for 8.75 million SWU per year, located near Buffalo, Wyo., where the company controls large coal and water resources.[9] A group involving Bechtel Corp., Union Carbide Corp., and Westinghouse Electric Corp. was considering the feasibility of a $1.5 billion facility. In another proposal, Electro-Nucleonics Inc. would lead four other U.S. companies in an engineering development and management group for enrichment by the gas-centrifuge method.[10]

Fabrication.—Westinghouse Electric Corp. announced plans for a $30 million, mixed oxide (uranium-plutonium) fuel plant, at capacity of several hundred tons per year, near Anderson, S.C. The fuels will be made from recycled fiissionable material. Construction was scheduled to start in 1974.[11]

Reprocessing.—In July, Allied Gulf Nuclear Services, Inc., submitted a license application and environmental report for new facilities, adjacent to its reprocessing plant at Barnwell, S.C., for conversion of uranyl nitrate to UF_6.

General Electric Co. planned reprocessing operations after engineering tests are made and an operating license is received at its Midwest Fuel Recovery Plant, near Morris, Ill. The first spent fuel arrived at the plant in January. Later in the year, the AEC issued a notice of intent to grant license.

The fuel fabricating and reprocessing plant of Nuclear Fuel Services, Inc. (NFS), at West Valley, N.Y., was shut down most of the year. NFS sought an AEC permit for expansion and equipment modification. The company planned to triple the existing 1-ton-per-day reprocessing capacity.

Scrap.—According to the AEC, 900 kilograms of Pu_{239}, 6.3 kilograms of Pu_{238}, and 4,000 kilograms of enriched uranium, valued at $32 million, $3.2 million, and $28.5 million, respectively, were recovered from AEC and commercial scrap during 1972. A centralized scrap management system was established to coordinate AEC efforts to recover valuable constituents from growing stocks of scrap materials.

Waste Management.—At the AEC's facilities at Hanford, Wash., and Savannah River, Aiken, S.C., new storage tanks were under construction for AEC-generated radioactive waste materials. Liquid wastes were evaporated to salt crystals for tank storage. Long-lived, heat-generating cesium-137 and strontium-90 were separated from other wastes and stored as liquid concentrates. A total of 135,000 gallons of waste was converted to 2,410 cubic feet of granular calcine at the AEC's Waste Calcining Facility, National Reactor Testing Station, Idaho, during the year. These materials were stored in stainless steel bins in underground concrete vaults.

The AEC has accumulated 85 million gallons of high-level wastes in underground tanks since inception of its storage program. Research and development continued on ultimate disposal methods and procedures.[12]

[12] Pages 61–64 of work cited in footnote 7.

A number of disposal methods were under consideration for long-term storage of high-level radioactive wastes at great depth in geological formations, which would reduce the burden of continual surveillance and control. This included storage in salt beds in Kansas; potash or limestone beds in New Mexico; basalt at Hanford, Wash.; deep trenches in the ocean floor; and deltaic areas, where actively accumulating sediments would increase the burial depth relatively rapidly. Other considerations were conversion of the trans-uranic radioisotopes to short-lived types and transport of wastes by rocket to the sun. The AEC, through the National Aeronautics and Space Agency, sought estimated costs for radioactive waste disposal in space, which, however, would depend on development of the space shuttle.

The AEC planned a dual approach—engineered surface storage (ESS) and underground storage—for high-level wastes from commercial reactors. In ESS, the wastes

would be reduced by solidification processes and stored in sealed canisters by reprocessors for a few years and then delivered to AEC facilities. The AEC planned to design and build an ESS facility for high-level wastes by 1979 or 1980. This installation would be designed so that wastes could be moved to underground storage if desired at a later date. A nationwide plan for waste disposal was under development by contract with Battelle-Northwest, Richland, Wash.

CONSUMPTION AND USES

Demand for U_3O_8 for commercial nuclear fuel use was gradually escalating as new orders were announced for nuclear power reactors. According to the AEC, nine units (13,870 megawatts) at eight locations were licensed for operation during the year. At yearend, the status of commercial reactor development in the United States was as follows:

Number of plants	Capacity (megawatts)	Status
29	14,683	Operable.
55	47,775	Under construction.
76	80,000	Under contract (reactors ordered).
Total 160	142,458	

The historical record for commercial orders for nuclear powerplants is as follows:

Year	Number of plants	Capacity (megawatts)
1965 [1]	20	8,456
1966	20	16,345
1967	30	25,427
1968	14	12,872
1969	7	7,208
1970	14	14,305
1971	20	19,921
1972	35	37,929
Total	160	142,458

[1] Excludes small prototype plants no longer in operation.

The trend continued toward larger capacity units, and, in September, a contract was signed for the first offshore-sited nuclear power station, along the New Jersey coast.[13]

The fast breeder reactor, introduced as early as 1986 in AEC contingency planning, was expected to have an impact on demand for U_3O_8 before the end of the century.[14] The liquid-metal fast breeder reactor (LMFBR), given priority in AEC breeder reactor planning, theoretically can

1978	6,400	105,700
1979	7,100	112,800
1980	5,100	117,900

[1] In the post-1980 period, through 1992, an additional 11,900 tons have been committed. In addition, 6,900 tons have been committed to foreign buyers, of which 4,800 tons were delivered prior to yearend 1972.

[2] Pre-1972 deliveries were 31,900 tons.

Source: U.S. Atomic Energy Commission.

An AEC uranium-marketing survey of 57 utility companies, 5 reactor manufacturers, and 19 uranium producers indicated an increase of 15,700 tons U_3O_8 in commitments during 1972.[16] A total of 11,600 tons U_3O_8 was delivered to the domestic market during the year. The status on total commitments, including foreign, was as follows:

	U_3O_8 *(tons)*
Deliveries and forward commitments, Jan. 1, 1972	114,100
Deliveries and forward commitments, Jan. 1, 1973	129,800
Deliveries, through Jan. 1, 1973	43,500
Forward commitments, Jan. 1, 1973	86,300

The survey also revealed that arrangements had been made for only 61% of

first-core fuels and progressively less for annual reloads.

Demand for separative work and enriched uranium also was expected to gradually accelerate. An Atomic Industrial Forum study concluded that world demand for enriched uranium will exceed cumulative supply by 1981, 8,700 SWU (about half the existing AEC capacity) will be needed to avoid a serious shortfall at that time, and a further increment at the same capacity will be needed in 1982.[17]

Ultrapure depleted uranium has potential use as a catalyst in the hydrocracking of shale oil. The addition of 10% depleted uranium to alumina and cobalt molybdates increased the hydrocracking activity of these catalysts, permitting lower operating temperatures and increased gasoline yields.[18]

STOCKS

The AEC reported private U_3O_8 concentrate inventories as follows, in tons U_3O_8, at the beginning of the year:

	1972	1973
In ore at mills	196	271
In process at mills	467	469
Inventory at mills	2,100	3,701
Inventory held by utility companies and reactor manufacturers (includes UF_6)	8,600	14,400
Total	11,363	18,841

In addition, the utility and reactor companies held inventories of enriched uranium.

Proposals for U_3O_8 sales from the AEC stockpile, announced late in 1971, were rescinded early in 1972 when it appeared that direct Government entry in the domestic U_3O_8 market might cause disruptions during a period of oversupply and depressed prices and would also tend to discourage private investment in uranium exploration. This stockpile, containing an estimated 50,000 tons U_3O_8, was accumulated during the 1960's as a result of cutbacks in AEC demand for fissionable material and before development of a private industrial market for uranium in power reactor fuels.

---

[17] Atomic Industrial Forum. The Time For Action Is Now. Nuclear Ind., v. 19, No. 10, October 1972, pp. 3–13.
[18] Chemical and Engineering News. New Use for Depleted Uranium. V. 50, No. 16, Apr. 17, 1972, p. 23.

The AEC planned to preproduce enriched uranium for future sales by operating its gaseous-diffusion enrichment plants at higher tails assay (0.275–0.3% U_{235}) while continuing the existing schedules for enrichment services, the additional feed material coming from the stockpile.[19] This program would avoid direct competition for U_3O_8 sales with the domestic uranium mining and milling companies, put the existing stockpile to productive use, and extend the period before additional enrichment capacity will be needed.

PRICES

A downward price trend for U_3O_8, which started in 1968, persisted during 1972 but appeared to have bottomed out and started a slight recovery. Available published data indicated that U_3O_8 prices were in the \$6–\$6.25-per-pound-U_3O_8 range for spot sales with immediate delivery and for starting prices in multiyear sales contracts with price escalation. The price approached \$8 per pound U_3O_8 in contracts extended post–1976.

According to the Nuclear Exchange Corp., foreign prices were about 20% lower than U.S. prices.[20] Foreign sales were often at \$5 to \$6 per pound U_3O_8; some sales were at prices below \$5 per pound U_3O_8.

The Commission of the European Communities (EC) reported an upward trend in prices and an agreement on future prices among its member countries. Early in the year, U_3O_8 prices in contracts covering 1972–78 were in the range of \$4.50 to \$6.60 per pound; later in the year, bids for the 1974–78 period ranged from \$5.95 to \$7.80 per pound. With these higher future prices, U.S. producers were in a position to submit competitive bids to consumers in the Community.[21]

The AEC announced a proposed price increase, effective August 14, 1973, in uranium toll enrichment services from \$32 to \$38.50 per SWU because of increased actual and projected costs, primarily for electric power. The AEC also intended to offer a reduced charge, \$36 per SWU, for services under proposed new long-term fixed-commitment contracts, which would permit better planning for enrichment services. Unit charges were scheduled to automatically increase 1% per 6 months, starting in January 1974, in order to partially offset future anticipated cost increases.

FOREIGN TRADE

Imports of U_3O_8 and other uranium compounds (mainly UF_6 and enriched UF_6) increased substantially during 1972. These materials were delivered to commercial plants for U_3O_8–UF_6 conversion and to the AEC for UF_6 enrichment services for foreign customers. Pursuant to section 161V, Atomic Energy Act of 1954, as amended, foreign uranium source materials cannot be imported for domestic consumption. The AEC announced plans to reconsider the lifting of this embargo within 2 years and possible repeal by 1978. The United States continued as a major world supplier of various radioactive and special nuclear materials.

[3] Includes plutonium, uranium-233, uranium-235, and enriched uranium.

WORLD REVIEW

Exploration for uranium in foreign countries continued at a slow pace for the most part, except in Australia, where activity was spurred by recent discoveries. Important new mines were under development in Australia, Canada, and the Territory of South-West Africa.

Foreign countries with major uranium resources—Australia, Canada, France, and Republic of South Africa—sent representatives to Paris in February to consider the problems of oversupply and depressed prices for uranium in world markets. At a second meeting in March, also in Paris, the group called for rationalization of production or other marketing arrangements. At a third meeting, in Johannesburg, South Africa, in June, an attempt was

[e] Estimate. [p] Preliminary. [r] Revised.

[1] In addition to the countries listed, Brazil, Czechoslovakia, Finland, East Germany, West Germany, Hungary, India, Japan, People's Republic of China, and the U.S.S.R. are believed to have produced uranium oxide, but information is inadequate to make reliable estimates of output level.

[2] Revised to none.

[3] Produced in part from imported material.

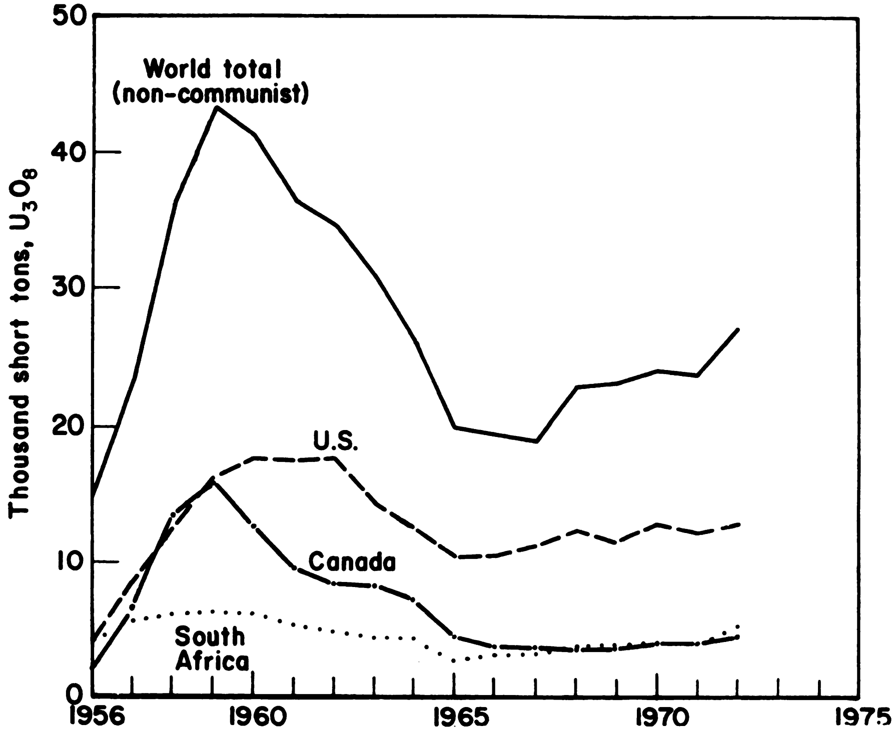

Figure 3.—World (non-Communist) production of uranium concentrate (U_3O_8).

made to present a united front to uranium buyers, and a quota system and minimum price standards were under consideration.[22]

Western Europe and Japan, the principal future (non-Communist) world markets for uranium outside the United States, continued efforts to assure supply of U_3O_8 and enriched uranium. Bilateral and multinational arrangements were made for U_3O_8 supply from Australia, Canada, Niger, and the Territory of South-West

---

[22] Mining Journal. Producers Meet in Johannesburg. V. 278, No. 7140, June 23, 1972, pp. 514–515.

Africa, and negotiations for uranium facilities involved Western Europe, Japan, and the producing countries, including the United States. Technical assistance was underway in uranium development, and joint manufacturing and marketing companies were formed.

In February, a French initiative resulted in a Western Europe study group, comprising seven nations, on gaseous-diffusion enrichment. The nations considered the pooling of knowledge and experience, development of cooperative programs, and the integration of activities on gaseous-diffusion technology.

The EC announced a nuclear program for better organization of the member Euratom nations to reduce or eliminate partitioning of the EC market and for resolving environmental problems inherent in nuclear energy.[23] Nuclear capacity was projected at 12,000 megawatts in 1975; 45,000 megawatts in 1980; a minimum of 100,000 megawatts (one-third of total electrical generating capacity) in 1985; and 620,000 megawatts in 2000. Orders for 75,000 megawatts of nuclear generating capacity were established as a minimum target during 1972–80. Cumulative Euratom demand was estimated at 55,000 tons U_3O_8 in 1985. U_3O_8 reserves within or controlled by the EC were 75,000 tons U_3O_8.

USAEC–EC representatives met to consider increased EC quotas for enriched uranium from the United States.[24] The existing quota was 215 tons SWU per year; the EC sought a ceiling of 450 tons SWU or assurance of supply on a nondiscriminatory basis. EC policy on future enrichment capacity and supply was under study.

During 1972, the EC concluded 21 contracts for 9,505 tons U_3O_8 and 12 toll enrichment contracts with the AEC for $192.7 million.

Rest-of-world operable nuclear capacity was nearly 20,000 megawatts at the end of the year, compared with nearly 15,000 megawatts operable in the United States.[25] Japan had the largest capacity under construction or planned. Foreign capacity was expected to reach 160,000 megawatts in 1980 and more than 2 million megawatts in 2000. Foreign non-Communist enrichment capacity was expected to remain lower than demand.

Australia.—Whereas uranium exploration slackened worldwide, it was at a record level throughout Australia, particularly in the Northern Territory and Western Australia. More than 80 Australian and international companies were directly or indirectly involved. Significant discoveries were reported in the Northern Territory, Queensland, South Australia, and Western Australia. Broad aerial and ground surveys and extensive drilling activity continued throughout the year.

Established reserves were estimated as follows:[26]

Location	Property	Reserves	
		Quantity (tons U_3O_8)	Average grade of ore (% U_3O_8)
Northern Territory	Ranger 1 and 3	91,000	0.34
Do	Nabarlek	11,600	2.37
Do	Jim Jim	NA	NA
Queensland	Westmoreland	15,400	.15
Do	Mary Kathleen	9,600	.12
Do	Miscellaneous	6,800	.15
South Australia	Lake Frome	13,800	.20
Do	Mount Painter	3,400	.11
Western Australia	Yeelirrie	50,000	.16

NA Not available.

This estimate indicates total reserves of more than 200,000 tons U_3O_8, exclusive of the Jim Jim deposit in the Northern Territory, where exploratory drilling continued at yearend. Some of these reserves, however, would not be economic at 1972 prices.

The Australian Atomic Energy Commission (AAEC) reported reserves, recoverable at $10 per pound U_3O_8, of 167,000 tons measured and indicated and 92,000 tons reasonably assured resources.[27] This reserve estimate excludes Western Australia.

Regardless of the magnitude of the reserve estimate, Australia was expected to become a major world supplier of uranium. The AAEC projected domestic demand of 2,000 to 3,000 tons U_3O_8 per year to 1990 and cumulative demand of 50,000 tons U_3O_8 to 2000; large supplies will be available for the export market. The AAEC anticipated a production rate of 12,000 tons U_3O_8 per year by 1982 and uranium exports valued at $200 million by 1980.

Ranger Uranium Mines Pty. Ltd. planned a mining rate of 3,000 tons U_3O_8 per year by 1976 at the Ranger mine, Northern Territory, the largest uranium mine in the country. The operation, to include a solvent extraction mill, was scheduled to produce 1 million tons of ore per year, averaging 0.20% U_3O_8.[28] In November, the Government approved contracts with two Japanese utility companies for delivery of 6.6 million pounds U_3O_8 during 1977–86. Another sales contract was announced for 17.3 million pounds U_3O_8, valued at more that $106 million, also with Japan, from the Nabarlek deposit, Northern Territory.[29] Nearly 10 million pounds U_3O_8 are committed in several sales contracts negotiated by Mary Kathleen Uranium Ltd. for the Mary Kathleen mine, Queensland, which was scheduled to re-open in 1974. At yearend, six uranium export contracts had been approved.

The discovery of uranium by Western Mining Co. Ltd. (WMC) at Yeelirrie, Western Australia, the first significant uranium discovery in the state, triggered a uranium rush which spread to several areas of the state. Hundreds of square miles were claimed, and other discoveries were reported during the year. Late in the year, WMC announced ore reserves of 35 million tons of ore, averaging 0.16% U_3O_8, in a mineralized area 5 miles long and 0.5 mile wide.

Australian authorities negotiated with the French and Japanese regarding the technical and economic feasibility of establishing a uranium enrichment plant in Australia.[30] The Minister for National Development announced a new policy providing access by Australian companies to nonclassified information on uranium enrichment held by the Government. Studies were underway in the various states to locate potential sites for enrichment plants. In October, the Government of Western Australia submitted a proposal to the Commonwealth Government for a $6.8 billion integrated industrial complex, including a 7,000-ton-per-year enrichment plant.

[29] Mining Journal. V. 279, No. 7164, Dec. 8, 1972, p. 466.

[30] Mining Journal. Australia Looks to Enrichment. V. 279, No. 7159, Nov. 3, 1972, p. 351.

According to the Minister for National Development, a decision on the proposed Jervis Bay nuclear powerplant was deferred for the second time, pending clarification of a number of circumstances, including safety criteria for the light water reactor (LWR) in the United States and a decision on the next generation of power reactors in the United Kingdom.

Canada.—Mine and mill production continued at only three operations—Rio Algom Mines Ltd. and Denison Mines Ltd., both in the Elliot Lake area, Ontario, and Eldorado Nuclear Ltd., Uranium City, Saskatchewan. U_3O_8 output increased 19%, reaching 9,796,000 pounds. Rio Algom operated its new Quirke mine at full capacity of 6,500 tons of ore per day from seven working levels.[31]

In February, construction started on the $50 million mine and mill complex of Gulf Minerals Canada Ltd., Gulf Oil Canada Ltd., and Uranerz Canada Ltd., at Rabbit Lake, northern Saskatchewan. An open pit mine will be developed to a depth of 400 feet. The new mill, with annual capacity of 4.5 million pounds U_3O_8, was scheduled for operation in 1975.[32]

As in 1971, exploration for uranium remained at a reduced level. A continuing soft market and uncertainty concerning Government policy on foreign ownership of uranium properties provided little incentive for investment in exploration.

Canada assumed a leading role as supplier of U_3O_8 in world markets. At the beginning of the year, outstanding contracts for Canadian uranium, for delivery in the early 1980's, totaled 61,000 tons, 85% of which was for export.[33] Commitments or guaranteed sales, including options, from 1966 through 1971 total 74,900 tons U_3O_8 primarily to Japan, West Germany, United Kingdom, and the domestic market.[34] In February, sale of 8.9 million pounds U_3O_8, valued at $60 million, was announced for delivery to Spain during 1974–77. This supply would be provided from the joint Denison Mines Ltd.–Government stockpile.

In August, atomic energy control regulations were amended, defining authority of the Atomic Energy Control Board (AECB) in withholding uranium export permits where prices or quantities specified in sales contracts are not in the public interest.

The Pickering-2 CANDU power reactor, the second of four 540-megawatt units planned at the site, was dedicated in February and performed well throughout the year. Pickering-3 and -4 were scheduled for completion in 1973 and 1974, respectively. In addition, construction of Bruce-1, first of four 800-megawatt units, was scheduled for completion in 1975.

An Atomic Energy of Canada Ltd. (AECL) study projected quantities of spent fuels as follows:[35] 28,000 cubic feet in 1980, 177,000 cubic feet in 1990, and 565,000 cubic feet in 2000. The AECL was assessing methods for long-term storage. The fuel cycle for natural uranium fuels, used in the CANDU reactor, does not involve reprocessing; the spent fuel is considered a waste product, and there are no current plans for recovery of any valuable constituents. The spent fuel bundles from the reactor are stored under water at the reactor site for 5 to 10 years. They then would be transferred to engineered long-term storage facilities (100 years or more), where they would remain subject to retrieval.

According to a National Energy Board forecast, power demand in Canada will increase fivefold by the end of this century, at which time more than one-half of electric generating capacity will be nuclear.[36] The Minister of State for Science and Technology estimated a cumulative investment of more than $10 billion in commercial nuclear development during the next 20 years.

France.—Mine production was at approximately the same level as in 1971. Average ore grade tended to increase. Efforts were made to improve operating methods and reduce costs.

In addition to estimated reserves of 45,000 tons U_3O_8 ($10 per pound) in metropolitan France, the Commissariat à l'Énergie Atomique (CEA) controlled uranium reserves totaling 50,000 tons U_3O_8 in Niger, Gabon, and the Central African Republic. Exploration by French companies, often joint projects, was conducted in Africa, Australia, Indonesia, and the United States.

The French negotiated in Western Europe, Australia, and Japan concerning cooperation in research and development in uranium enrichment, based on French gaseous diffusion technology. A multinational study group was organized with private and public interests in Belgium, West Germany, Italy, Netherlands, and the United Kingdom (Sweden and Spain were added later in the year) to form a new company, Eurodif, to work with the CEA on economics of a commercial operation.

The Phénix 250-megawatt prototype LMFBR was scheduled for operation at Marcoule in 1973. A cooperative agreement was concluded with West Germany and Italy on a 1,000-megawatt fast breeder, construction of which would start in 1974. A 10-year joint fast-breeder program was negotiated with Japan.[37] Technicatome, an LMFBR engineering company, was created by the CEA (90%) and Electricité de France (10%).[38] This company let a contract for bid specifications for a 1,200-megawatt fast breeder.

Westinghouse Electric Co. joined with Péchiney-Ugine-Kuhlmann (PUK) in a LWR nuclear fuel venture.

Germany, West.—The Government budgeted $8 million for sponsoring uranium exploration in 1972. Projects were underway in northeast Bavaria; the Salzburg, Arlberg, and Tirol areas of Austria; Niger, Mali, Ghana, Togo, and the Territory of South-West Africa; Australia; Canada; and the United States.[39] The Government withdrew financial support for the mining project at Rossing, South-West Africa. With an 8.5% interest in the Arlit deposit in Niger, West German shipments of uranium concentrate will start in 1974 and reach 150 tons per year. Exploration activity in Australia was with Italian and Australian interests. In Canada, Uranerz Canada Ltd. has a 49% interest in the Rabbit Lake project in Saskatchewan. In the United States, joint exploration with Atlantic Richfield Corp. was underway in the Chama Basin, N. Mex., and on concessions in Wyoming and Utah.

The pilot gas-centrifuge cascade at Juelich operated for a full year with reportedly good results. Uran-Isotopentrennungs G.m.b.H. (URANIT) was building a West German prototype centrifuge facility at Almelo, Netherlands, as part of a tripartite agreement on enrichment development with the Netherlands and the United Kingdom. The Almelo plant was scheduled for operation at a rate of 5 tons separative work per year early in 1973 and at 25 tons per year when additional cascades are completed later in 1973.

According to the Minister of Science, separative capacity per centrifuge was increased sixfold during the past 10 years. The decision was made to develop capacity of 300 tons per year by 1973 and 3,000 tons per year by 1980.

The Science Ministry projected cumulative U_3O_8 demand at 25,000 tons in 1980. Annual demand was 700 tons in 1972 and will be an estimated 5,500 tons in 1980. Separative work requirements were to be as follows, in kilogram SWU's:

Year	Annual	Cumulative
1975	1,700	5,000
1980	3,500	18,500
1985	8,500	78,000

Plans were made to start construction on a $333 million, 300-megawatt fast breeder reactor (FBR) at Kalkar, near the Netherlands border, in 1973. The project was sponsored by an international consortium comprising West Germany, Belgium, the Netherlands, and Luxembourg.[40]

[40] Hafele, W., and G. Kessler. SNR: The German-Benelux Fast Breeder. Nuclear News, v. 15, No. 3, March 1972, pp. 48–53.

Japan.—The Japanese Government sought means of diversifying uranium supply sources and assuring future supply by seeking joint foreign agreements on exploration, mining, and enrichment services. In February, Japanese utility companies concluded contracts with the United States for purchases of up to 369 tons (335 metric tons) of enriched uranium per year for 26 years. Cooperative agreements were also made with France, Australia, Canada, West Germany, and the United Kingdom. Survey missions were active in several African countries and Mexico. An Enrichment Survey Committee was formed to study proposals for Japanese participation in foreign enrichment projects.

Negotiations for enriched uranium included construction of an enrichment plant in Japan or in the United States. Reynolds Metals Co. proposed a joint venture with a number of Japanese utility companies.[41] As part of a United States-Japan trade agreement, Japan would prepay $320 million for 10 million SWU's in enrichment services, the uranium coming from the United States preproduced inventory of enriched uranium. A joint working group would be formed with the USAEC on the feasibility of a joint gaseous diffusion facility in the United States.[42]

Two major Japanese power companies will purchase 3,300 tons U_3O_8, valued at $40 million, from Ranger Uranium Mines Ltd., Northern Territory, Australia, during 1977–86; 1,000 tons U_3O_8 from Mary Kathleen Uranium Ltd., Queensland, Australia; and 2,200 tons U_3O_8 from Queensland Mine Ltd., Australia.[43]

A White Paper, prepared by the Science and Technology Agency (STA), predicted a uranium supply crisis if the Japanese did not participate in foreign enrichment and develop their own enrichment technology. Research and development were centered around the Japanese Atomic Energy Research Institute and Nuclear Fuels Corp. The Uranium Enrichment Technical Development Council, an advisory group to the Japanese Atomic Energy Commission (JAEC), recommended a national research and development project on gas centrifuge technology and fundamental research on gaseous diffusion. Ten centrifuges, installed at Tokai, were scheduled for operation in 1973.

Two nuclear fuel processing and fabricating companies were formed—Mitsubishi Nuclear Fuel Co. and Japan Nuclear Fuel Co. Plans called for UO_2 and fabrication capacity of 450 tons per year by 1975.[44] Allied Gulf Nuclear Fuel Services, Inc., a United States firm, and the Mitsubishi Group agreed to a $130 million joint-venture nuclear fuel reprocessing plant. Initial capacity would be 5 tons per day, operable in 1983 in either the United States or Japan.

Studies were also initiated on radioactive waste management. STA considered the more remote Japanese islands as possible sites for waste storage. Islands off the south and west coasts of Kyushu were investigated.

According to the JAEC, nuclear generating capacity was nearly 1,300 megawatts in 1972. Projections were 14 nuclear powerplants (8,000 megawatts) in 1975; 32,000 megawatts in 1980; 60,000 megawatts in 1985; and 100,000 megawatts in 1990.

The Central Electric Power Council forecast a 10.5% growth rate for electric power demand through fiscal year 1980 and the need for 149,070 megawatts of new capacity (66,880 megawatts nuclear). Plans called for 34,100 megawatts nuclear capacity in 1980 and a further 5,700 megawatts under construction in 1980–81.

South Africa, Republic of.—According to the Chamber of Mines of South Africa, production of U_3O_8 was slightly reduced from the 1971 rate. Uranium was recovered as a byproduct at nine gold mines and was the primary product at operations of West Rand Consolidated Mines, Uranium Section. The principal uranium-producing mines were Vaal Reefs and Buffelsfontein. Material processed for uranium totaled 16.1 million tons at an average grade of 0.5 pounds U_3O_8 per ton.

Although only 11 mines were uranium producers, 27 mines were capable of supporting uranium production, and 17 mines had uranium extraction plants.

Reserves were reported at 300,000 tons

[43] Metal Bulletin. Ranger Concentrates for Japan. No. 5729, Sept. 1, 1972, p. 18.

[44] American Nuclear Society. New Companies Formed. Nuclear News, v. 15, No. 1, January 1972, p. 42.

U_3O_8 ($10 per pound U_3O_8), a substantial increase over previous reports, and apparently included approximately 100,000 tons U_3O_8 for the Rossing property, South-West Africa.

A calcined uranium product of 98%–99% U_3O_8 purity was recovered as a byproduct at the Palabora copper mine, where U_3O_8 production was started in 1971. Tailings from copper concentration, after desliming and removal of magnetite, were fed to a recovery plant at an average rate of 22,000 tons per day. Gravity concentration and shaking tables produced three product streams, including a uranothorianite concentrate containing 5% U_3O_8, which went to a chemical extraction plant, where uranium (and thorium) were recovered by leaching and solvent extraction.[45]

Tenders were let for South Africa's first nuclear powerplant, at Duinefontein, north of Cape Town. This 500-megawatt installation was scheduled for operation in 1979.

United Kingdom.—The Atomic Energy Authority (AEA) continued development work on the MK II and MK III (advanced gas-cooled reactors—AGR), the steam-generating heavy-water reactor, and the FBR.[46] Progress was made on construction of the 250-megawatt prototype FBR at Dounreay, which was scheduled for completion in 1973. Development work continued on a program for a 1,000-megawatt FBR.

The first cascade of the gas-centrifuge uranium enrichment plant at Capenhurst went into operation. This project is part of a tripartite (United Kingdom, West Germany, and the Netherlands) program for development of a commercial enrichment capability. British Nuclear Fuels, Ltd., was adding 100 centrifuges weekly and planned completion of a 15-ton-per-year pilot plant in 1973.

The first nuclear development program, including nine commercial nuclear powerplants, based on natural uranium-gas-graphite reactors, was completed. Under the second program, which was based on the AGR, using enriched uranium fuel, six plants comprising 14 reactors (8,750 megawatts) were under construction by the Central Electricity Generating Board at yearend.[47] Operations at several plants were slowed by a corrosion problem concerning 9% chrome steel. This problem was also likely to affect AGR planning.

U.S.S.R.—The 350-megawatt (thermal), dual-purpose (electric power and desalination) FBR at Shevchenko, on the northeast shore of the Caspian Sea, went critical during the year. A problem was encountered due to fuel pin swelling. The U.S.S.R. nuclear power program is based on PWR's and large-capacity graphite-water reactors. A 2,000-megawatt, two-unit installation of the latter type was under construction at Leningrad. Plans call for 30,000 megawatts of nuclear electric capacity by 1980. A large-capacity LMFBR was planned for the early 1980's. In addition to the Shevchenko unit, a 600-megawatt FBR was under construction in the Ural Mountains.[48]

Other Countries.—In Western Europe, all nations had interest in uranium development and/or plans for internal nuclear power development. In Austria, construction was started on the first nuclear powerplant, a 700-megawatt BWR, located at Zwenterdorf, on the Danube River.

Belgium had an 870-megawatt unit and two 390-megawatt units under construction at Tihange and Doel, respectively.

In Denmark, the Jutland-Funen Elecricity Cooperation (ELSAM), a federation of companies with seven power stations, requested meetings with the Danish Atomic Energy Commission on a first nuclear unit, of 600-megawatt capacity, proposed for the Copenhagen area. The Commission announced discovery of a uranium deposit, covering an extensive area in the Kvane Mountains of southwest Greenland.[49]

In Finland, two units (860 megawatts) of U.S.S.R. design were under construction at Loviisa, east of Helsinki, and a third unit was planned near Rauma, on the west coast. According to the Finnish State electric utility company, planning includes a

nuclear power unit every 2 years.[50] The third unit will be the first involving private funds; 16 industrial firms will own 60%, the remainder being publicly owned.

In Greece, the Public Power Corp. and the Hellenic Atomic Energy Commission planned a 600-megawatt plant, the first of eight proposed. Three units would be in operation in 1985 (21% of total generating capacity), and nuclear capacity totaling 4,200 megawatts would be in operation in 1990 (36% of total generating capacity).[51]

AGIP Nucleare, Italy, was active in uranium exploration in Australia, Somalia, the United States (jointly with Denison Mines Ltd. in Wyoming, Montana, and South Dakota), and Zambia. According to Ente Nazionale per l'Energia Elettrica (ENEL), the State-owned electric utility company, future operable nuclear capacity would be as follows: 5,500 to 6,500 megawatts in 1980; 16,000 to 20,000 megawatts in 1985; and 44,000 to 60,000 megawatts in 1990.

In the Netherlands, a gas-centrifuge enrichment facility (annual capacity 25,000 kilograms SWU) started operations late in the year. According to the Ministry of Economic Affairs, the Netherlands nuclear power program, based on its share in EC projections, was as follows: 2,000 megawatts in 1980; 8,000 megawatts in 1990; and in excess of 20,000 megawatts in 2000, when about half the total installed capacity would be nuclear.

In Spain, the Ministry of Industry authorized Empresa Nacional del Uranio S.A. (ENUSA) to evaluate domestic uranium resources; develop mining and processing techniques; conduct enrichment, nuclear fuel, and fuel-reprocessing studies; and negotiate with foreign suppliers on behalf of Spanish companies. ENUSA was in charge of development of the Ciudad Rodrigo uranium deposit, Salamanca province, and exploration in Soria and Sevilla provinces. Reserves were estimated at 10,000 tons U_3O_8 ($10 per pound U_3O_8); 9,000 tons ($10–$15); and 5,000 tons ($15–$20). The Spanish Government completed a $60 million purchase from Canada for 8.9 million pounds U_3O_8 (average $6.50 per pound) for 1972–77.[52] Late in the year, commitments were made for two more PWR's in the 900- to 1,000-megawatt class, the sixth and seventh PWR's from Westinghouse in little more than 1 year. The Spanish National Electricity Plan called for 8,000-megawatt nuclear capacity in 1980 and 15,000-megawatt nuclear capacity in 1983.

[50] Engineering News-Record. Soviet-Engineered Nuclear Plant Uses U.S. and Western Systems. V. 189, No. 2, July 13, 1972, p. 18.

[51] American Nuclear Society. Nuclear News Briefs. Nuclear News, v. 15, No. 2, February 1972, p. 51.

In Sweden, the Geological Survey sought increased funds for uranium exploration, including airborne surveys in Lappland, where uranium was discovered.[53] The State Power Board and A.B. Atomenergi planned a 3-year research-and-development project at Ranstad, where grade is low (0.03% U_3O_8) and high-cost reserves extensive (270,000 tons U_3O_8). This project was aimed at greater operating efficiency, possible recovery of molybdenum and vanadium, and improved extractive methods. The Ranstad mine was maintained on a standby basis because production costs exceeded the world price for uranium. Six nuclear powerplants were under construction, and a 8,200-megawatt nuclear capacity was expected in 1980.

In addition to a 1,000-megawatt nuclear capacity operable in Switzerland, six large capacity plants were approved or being planned.

Radiometric anomalies were recorded over an extensive area in Slovenia, Yugoslavia. Further investigation led to discovery of a possibly economic deposit at Zirovski Vrh, where development was underway. Plans continued on the Krsko nuclear powerplant, a Slovenia-Croatia project and Yugoslavia's first.

Among the Communist-bloc nations in Europe, a 440-megawatt PWR under construction in Bulgaria was scheduled for completion in 1975; a second unit was planned at the same site. A small capacity operable unit in Czechoslovakia is gas cooled and heavy water moderated; four PWR's were committed.

In Latin America, nuclear power was considered important to future development in Argentina, where several CANDU-type plants (1,900 megawatts) were planned for 1980.[54] A CANDU installation at Atucha, 60 miles northwest of Buenos Aires, is Latin America's first nuclear powerplant and was expected to be operable in 1973, 1 year behind schedule. No decision was made on the type of reactor planned for Cordoba province. Exploration for uranium deposits was underway in four regions. Domestic reserves were estimated at 16,000 tons U_3O_8. The Comisión Nacional de Energía Atómica planned a mine and mill in Sierra Pintada, Mendoza Province, where production at a rate of 400 tons U_3O_8 per year was scheduled for 1977.

Homestake Mining Co. expressed interest in a uranium exploration program in Bolivia.

In Brazil, Companhia Brasileira de Tecnologia Nuclear (CBTN) was organized to construct a mill for processing ore from Poços de Caldas, Minas Gerais, and plan a nuclear fuels industry. Uranium was discovered near Belo Horizonte, Moeda Range, Municipio Brumadinho, with West German assistance; drilling was planned. Late in the year, construction started on a PWR in the 600-megawatt category at Angra dos Reis, Sepetiba Bay, 90 miles southwest of Rio de Janeiro.

Mexico made plans for its first nuclear unit, a 660-megawatt BWR at Laguna Verde, 55 miles north of Vera Cruz. A joint United States-Mexico group will study possibilities for nuclear electric power and water desalination.

Among the African nations, Société Nationale de Recherche et d'Exploitation Minière (SONAREM), the State mining agency in Algeria, reported a uranium discovery in the Hoggar area, deep in the Sahara Desert. In Angola, a joint exploration venture between the Portuguese Nuclear Energy Board and Urangesellschaft m.b.h. covered the Dondo, Malange, and Moxico areas. Uranium concentrate production of Société des Mines de l'Air at Arlit in Niger was at full capacity. Plans to double output were delayed. Japanese-CEA exploration established ore reserves at Akokan; a feasibility study was made for a mine-mill project. Exploration by Somiren S.p.A., subsidiary of Ente Nazionale Idrocarburi, the Italian national company, continued in Somalia, where large, low-grade resources were identified.

The West German Government withdrew financial support at the Rossing project, Territory of South-West Africa, where production was scheduled for 1976. Urangesellschaft m.b.h. may continue support with Rossing Uranium Ltd. A number of companies, including the major South African mining groups, continued exploration in the area. Western Knapp Engineering Division of Arthur G. McKee and Co., San Francisco, Calif. and Power Gas Ltd., London, were granted a contract for design, engineering, procurement, and construction at the project.[55]

In the Far East, India planned self-sufficiency in uranium resources and emphasis on CANDU-type reactors to avoid dependence on foreign enriched uranium. Uranium Corp. of India Ltd., a Government-owned company, planned to deepen the Jaduguda mine, Bihar, to 2,000 feet. Reserves in Bihar were estimated at 50,000 tons U_3O_8 in low-grade ore. Mill capacity of 1,000 tons of ore per day would supply the four 200-megawatt CANDU units under construction. The company also planned a uranium-recovery circuit at the Surda copper refinery, Bihar. A Ten Year Profile on Atomic Energy, presented by the Indian Atomic Energy Commission, proposed 2,700 megawatts of nuclear capacity by 1984, design and construction of a prototype FBR, and development of gas-centrifuge technology, a nuclear fuels industry, and fuels-reprocessing facilities.

In Pakistan, a United Nations Development Program was assessing the Dera Ghazi Khan deposits, where drilling was in progress. A pilot plant at Lahore will process 1,000 pounds of ore daily. The Japanese were assisting the Pakistani Atomic Energy Commission (PAEC) in uranium exploration. Pakistan's first nuclear powerplant, located 27 miles west of Karachi, went to full power operation in October. It is a 125-megawatt CANDU type reactor, built with Canadian assistance.

In Taiwan, two 600-megawatt BWR's were under construction at Chinsan, and two larger-capacity BWR's were ordered for a location in the north.

TECHNOLOGY

The isotope U_{236} was observed for the first time in natural ores on earth. This observation followed its discovery in lunar samples from the Apollo 14 flight. Extremely sensitive mass spectrometers that masked U_{235} were used in detecting the U_{236}. U_{236} was more abundant in the lunar samples.

A new concept on uranium deposition led to a better understanding of the origin of Tertiary uranium deposits in Wyoming.[56] According to this theory, a geochemical cell develops with oxygenated ground water in a reducing environment in sediments below the water table. Destruction of carbonaceous material, oxidation of pyrite, and accumulation of uranium occur in a wave or front ahead of the invading oxidizing environment.

New equipment was under development for use in uranium exploration and radiation monitoring. A highly sensitive scintillation detector, developed by the Westinghouse Nuclear Instrumentation and Control Department, will monitor gamma radiation particles in air. It was designed for environmental safety surveillance in and near nuclear powerplants.[57]

A technique, called Track Etch, was developed at General Electric Co. laboratories for minimum exploration time with no environmental disturbance. The instrument measures the concentration of radon gas and records data on a special film, which was placed in small plastic cups. The technique may be used in early exploration to delineate favorable trends or zones, in conjunction with airborne surveys, in defining radon anomalies near known ore bodies, and in analyzing radon concentration in exploratory drilling by lowering the film cups into drill holes.[58]

Another procedure measures the earth heat flux in drill holes, anomalous radioactive heat sources being indicative of the presence of uranium.[59]

A neutron source, such as Californium$_{252}$, may present a fairly accurate estimate of grade in drill holes, reducing the need for chemical assays.[60] The ore zone is irradiated with bursts of fast neutrons. Neutrons detected between bursts are indicative of delayed neutron emissions from fission in a uranium source.

Studies were reported on uranium recovery from seawater. Investigations by the United Kingdom Atomic Energy Authority indicated that the uranium concentration in seawater is 15.3 tons per cubic mile, with uranium in solution as the $UO_2(CO_3)_2$ complex, and that the uranium may be recoverable at £15,000 to £30,000 per metric ton U (which corresponds approximately to $70 to $140 per pound U_3O_8). Hydrated titanium oxide in granular form was tested as a uranium absorber in a pilot plant which treated 4,000 cubic meters of seawater per week.[61]

The Power Reactor and Nuclear Fuel Development Corp. of Japan developed a simple, relatively low-cost method for extraction of uranium from seawater.[62] The absorbent material was sawdust, processed with 3.5% hydrochloric acid and soaked in 0.2% caustic soda solution. In a test, 1 gram of the absorbent was sufficient to extract uranium from a solution of 0.003 milligram of ionized uranium per liter.

Stress measurements in mines, laboratory tests on compressive rock strength, geologic study to evaluate tectonic stresses, and a survey on mining conditions and pillar configuration were conducted in the Elliot Lake mining district, Ontario, Canada.[63] Considerations in evaluating pillar design were pillar size, depth of mining, rate of extraction, and stress data.

New solution mining techniques for uranium were under investigation. In one procedure, oxygen was injected as an oxidant into development and production wells in a grid pattern to drive formational water from the producing area. An acid solution was then injected into the ore body, and the leach liquor containing the dissolved uranium salts was pumped to the surface.[64] In another procedure for in-situ uranium leaching from sulfide or carbonate ore bodies, oxygenated foam, air, or other oxygen-bearing gas was injected prior to or simultaneous with ammonium carbonate, sodium carbonate, or sulfuric acid as the leach solution.[65]

The Atomic Energy Board, Republic of South Africa, reported research and pilot-plant tests on a continuous countercurrent ion exchange column. More than 99.5% of the soluble uranium was recovered with a resin inventory less than one-third of that required by fixed-bed ion exchange.

A wet process for UF_6, in contrast to the usual dry method of obtaining UF_4 as an intermediate step, was under study in Japan.[66] Uranium is dissolved with hydrochloric acid and recovered by electrolytic reduction with a special ion-exchange resin and platinum electrode. The benefits reportedly were fewer processing stages, and lower temperature needed (100° C), resulting in reduced cost in plant and operation.

ACE nuclear fuels research was directed primarily toward behavior properties and performance data on uranium-plutonium oxide LMFBR fuels.[67] The objective was a fuel capable of operating efficiently in an LMFBR environment (1,200° to 1,400° F) while achieving an average burnup of 100,000 megawatt-days per ton (MWD/T) of fuel and a peak burnup of 150,000 MWD/T. Mixed (uranium-plutonium) oxide fuel pins were tested in Experimental Breeder Reactor 2 at the National Reactor Testing Station, Idaho. Data were also obtained on mixed carbide and nitride fuels, which may afford higher thermal efficiencies and higher fuel densities necessary for a high breeding ratio.

[67] Pages 13–15 of work cited in footnote 7.

Studies on irradiation performance, safety characteristics, fuel-cycle costs, and fuel pin design for nitride fuels at Battelle Memorial Institute indicated certain advantages of this type of fuel.[68] The mixed nitride fuels exhibited thermal stability at temperatures exceeding 2,500° C, low swelling rates as long as temperatures that permit agglomeration of fission gases are avoided, low percentages of fission-gas release, and high burnup rates without degradation in fuel behavior.

In the FBR, high fuel burnup would result in significant fission-produced impurities. Certain impurity particles were identified by scanning electron microscopy.[69] Their influence on fracture stress was investigated at room temperature. Purification procedures reducing both particle size and number of particles improved fuel strength.

In a temperature range where gas bubble growth causes nuclear fuel swelling, the rate of swelling is an exponential function of the temperature, indicating that the process is fundamentally associated with diffusional creep processes. Studies were made on external diametrical swelling rates in oxide, nitride, and carbide fuels at temperatures to 1,900° C.[70] Analysis of gas-bubble growth indicated that the long-term creep strength of nuclear fuels and cladding is an important factor in controlling swelling.

Fuel swelling is caused by an accumulation of fission products in pore spaces, which also influence the strength and ductility of the fuel and its cracking and swelling behavior. The effects of porosity in sintered polycrystalline UO_2 on fuel strength and deformation characteristics were assessed over a wide temperature range (500° C, 1,250° C, and 1,600 C). Porosity was varied by use of naphthalene in UO_2 powder. At the lower temperatures, fracture was brittle and transgranular and initiated from large pores present after fuel fabrication. Increased porosity caused marked reduction in strength. At the higher temperatures, plastic deformation preceded fracturing, and the effects of porosity were more complex.[71]

Cold-pressed and sintered UO_2 pellets, a common nuclear fuel form, and UO_2 powder were the subjects of a study on sintering behavior. An attempt was made to develop improved correlations and information on the mechanism of sintering.[72] The ratio of pore size to particle size was considered important. Green density below 40% of the theoretical led to progressively reduced rates of sintering but did not affect the sintering law or the apparent activation energy for sintering.

Efforts were made to improve fabrication techniques for uranium mononitride (UN) fuels, which have a high melting point, good thermal conductivity, and stability under radiation. During UN preparation, oxygen can enter the lattice; it was therefore necessary to establish the maximum oxygen solubility in the lattice under various temperatures and pressures. At 1,600° C, 4,400 parts per million of oxygen can enter the lattice; above this temperature, oxygen solubility decreased slightly.[73]

Research on mixed fuels in test reactors, preparatory to high endurance capabilities and high burnup rates necessary in the commercial LMFBR, indicated a need for fuel-sodium reaction studies and metallurgical studies on the swelling problem.[74]

A project was underway to develop a chemical flowsheet for converting uranium nitrate solution to ceramic-grade UO_2 powder having desired properties for uniform blending with ThO_2 powder and for pressing and sintering into high-density, homogenous fuel pellets for the LWBR. The LWBR fuel is ThO_2 in which 1%-6% U_{233} in UO_2 form is dissolved. Studies on UO_2 production included the effects of nitric acid content of uranyl nitrate, temperature of precipitation, pH of solution, and time of digestion on uranate cake consumption.[75]

During refueling at a commercial reactor site, flattening was discovered in sections of some unpressurized fuel rods in a PWR. The AEC made a study of fuel performance of zircalloy-clad unpressurized fuel rods. Densification and movement of the pellets apparently caused open space within the rods, and greater pressure on the outside caused flattening of the cladding. This appeared more likely to take place in unpressurized rods. Beginning in November, the AEC required applicants and licensees to prepare new safety analyses to include possible effects of fuel densification and associated phenomena.

Investigations on fuels, nuclear materials, and reactor components continued at LMFBR development facilities of the AEC. These projects included Experimental Breeder Reactor 2 at the National Reactor Testing Station, Idaho; the Fast Flux Test Facility, under construction near Richland, Wash.; and the Liquid Metal Engineering Center, near Canoga Park, Calif. Other AEC-sponsored projects included the high-temperature, gas-cooled reactor at ORNL, Pacific Northwest Laboratory, and cooperative work with Gulf General Atomic Co, (GGA), San Diego, Calif.; the Gas-Cooled Fast Reactor at Argonne National Laboratory, ORNL, and with GGA; the Molten-Salt Breeder Reactor at ORNL; and the light-water breeder reactor, for which a demonstration core was under development for installation at the Shippingport, Pa., station in 1975.

A new boiling water reactor (BWR) design, called the BWR/6, went on the market. The manufacturer announced that it produces 20% more power without increased size of reactor and supporting systems. Other advantages were increased coolant circulation capacity, increased capacity for steam separators and dryers, and more fuel bundles with improved internal arrangement in the reactor to give greater heat output.[76]

Progress was made toward development of a commercial offshore, barge-mounted nuclear powerplant. Facilities were planned for the manufacture of four plants per year, starting in 1975.[77] A "tuned hemisphere" floating platform concept offers stability and less costly construction. The platform is spherical, using the principle of secondary mass, which tunes natural roll frequency lower than that of conceivable waves.

In offshore powerplant siting, thermal effects would be minimized; the ocean provides an enormous heat sink for plant effluent. Studies indicated a water temperature rise of less than 2° F within a 5-acre area.[78] Underground reactor installation also was considered feasible; this would alleviate some environmental objections, although construction costs may be 10% higher than that for surface plants.

A rapid and sensitive method using uranium was under development for calibrating meters to measure oxygen concentration in sodium for the LMFBR.[79] Accurate measurement of oxygen concentration in the sodium coolant was considered important; oxygen concentration in the coolant is related to corrosion, which would lead to transfer of radioactive materials from the reactor core to other parts of the primary LMFBR system.

Vanadium

By Harold A. Taylor, Jr.[1]

Domestic demand for vanadium was still weak in 1972, compared to the high of 1969, although it was stronger than last year. Overseas demand was also weak but becoming stronger. Domestic production, expressed as vanadium pentoxide recovered, did not change significantly from last year because the production decrease resulting from the shutdown of the Rifle mill was balanced by increases in output at other facilities. Exports of both ferrovanadium and vanadium ores and oxides were much smaller than in 1971, while imports of ferrovanadium were much larger. The Government sold all of its surplus vanadium pentoxide in May.

Legislation and Government Programs.—The General Services Administration (GSA) sold all its excess vanadium pentoxide, 5.6 million pounds, to three metal trading firms in May. A condition of sale was that the material could not be sold abroad as vanadium pentoxide. It must be converted to another vanadium product in this country in the event of export. The material sold consisted of 87 lots, the vanadium pentoxide contents of which ranged between 85% and 90%.

As of December 31, 1972, the Government had an inventory of 2,800 short tons of vanadium, the entire quantity in the national stockpile. Of this total, 1,200 tons was held as ferrovanadium and 1,600 tons was held as vanadium pentoxide.

Table 1.—Salient vanadium statistics

(Short tons of contained vanadium)

	1968	1969	1970	1971	1972
United States:					
Production:					
Ore and concentrate:

[1] Measured by receipts of uranium and vanadium ores and concentrates at mills, plus vanadium recovered from ferrophosphorus derived from domestic phosphate rock.

DOMESTIC PRODUCTION

The principal domestic source of vanadium continued to be the Colorado Plateau uranium-vanadium ores, but by an even more slender margin than in 1971. Both Arkansas vanadium ore and Idaho ferrophosphorus supplied an increased amount of vanadium. Most of the producing facilities processed such materials as vanadium-bearing oil residues, spent catalysts, vanadium-bearing residues from titanium dioxide production, and foreign vanadium-containing slags. Vanadium obtained by processing imported vanadium-

Table 2.—Recoverable vanadium of domestic origin produced in the United States, by State

(Short tons of contained vanadium)

State	1968	1969	1970	1971	1972
Colorado	3,492	W	W	W	W
Utah	563	W	257	226	188
Other States[1]	2,428	W	W	W	W
Total	6,483	5,577	5,319	5,252	4,887

W Withheld to avoid disclosing individual company confidential data; included in total.

[1] Includes Arizona 1968–69, Arkansas 1968–72, Idaho 1968–72, New Mexico 1968–72, South Dakota 1970, and 1972.

containing slags was not included in the recovered vanadium pentoxide figures shown in tables 1 and 4.

Most of the vanadium obtained from domestic uranium-vanadium ores in 1972 was recovered at the Rifle mill of Union Carbide Corp. The Soda Springs, Idaho, plant of Kerr-McGee Corp. and the Hot Springs, Ark., plant of Union Carbide Corp. recovered vanadium from byproduct ferrophosphorus obtained in elemental phosphorus production. The Hot Springs, Ark., plant also recovered vanadium from Arkansas vanadium ore. Other producers of vanadium pentoxide or ammonium metavanadate from domestic ores and/or residues included the Edgemont, S. Dak., mill of Susquehanna-Western, Inc., the Wilmington, Del., plant of The Pyrites Co., Inc., the Texas City, Tex., plant of Gulf Chemical & Metallurgical Corp., and the Moab, Utah, mill of Atlas Corp.

Union Carbide shut down its mine and milling operations at Rifle, Colo., on August 1 and began transferring its vanadium milling circuit to Uravan. It was estimated that installation of the circuit at Uravan would take about 9 to 10 months, and meanwhile the Rifle mill will be maintained on a standby status. Vanadium liquor produced at the new Uravan operation will be shipped to Rifle where ammonium metavanadate will be precipitated, vanadium oxide produced, and the product stored for shipment. Management cited the following reasons for the shutdown and transfer: the depressed uranium prices caused by delay in nuclear powerplant construction, the diminished ore reserves and relatively low ore grades, and the increased cost caused by meeting new regulations concerning radon daughter exposure in underground mines.

Atlas Corp. began preparations to resume production of vanadium from Colorado Plateau ores. Its plans included the reinstallation of a vanadium recovery circuit at its Moab mill. However, the circuit will not be entirely completed until late 1975 or early 1976. Ongoing exploration has revealed a large deposit of uranium-vanadium ore worth an estimated $30 to $50 million located on leased properties in the Sage Plains area of Utah. In addition, the company signed an agreement to buy all the American Metals Climax (AMAX) uranium-vanadium properties in the Uravan minerals belt of Utah and Colorado, estimated to be worth another $30 to $50 million, and finalized the sale in early 1973. The company expects to be in a strong position to process ores on a toll basis and to bid for uranium-vanadium ore reserves.

Table 3.—Mine production and recoverable vanadium of domestic origin produced in the United States

(Short tons of contained vanadium)

Year	Mine production[1]	Recoverable vanadium[2]
1968	7,105	6,483
1969	5,737	5,577
1970	5,793	5,319
1971	5,547	5,252
1972	4,699	4,887

[1] Measured by receipts of uranium and vanadium ores and concentrates at mills, vanadium content.

[2] Recoverable vanadium contained in uranium and vanadium ores and concentrates received at mills, plus vanadium recovered from ferrophosphorus derived from domestic phosphate rock.

Table 4.—Production of vanadium pentoxide in the United States[1]

(Short tons)

Year	Gross weight	V_2O_5 content
1968	12,105	10,976
1969	12,120	10,542
1970	11,035	9,986
1971	10,492	9,448
1972	10,410	9,367

[1] Includes vanadium pentoxide and metavanadate produced directly from all domestic sources, plus small byproduct quantities from imported chromium ores.

The Pyrites Co., a subsidiary of Rio Tinto-Zinc Corp., Ltd., placed its new vanadium facility at Wilmington, Del., in partial operation, and was producing ammonium metavanadate by the end of the year. Plans called for production of fused flake vanadium pentoxide later; feed is expected to consist largely of residues.

CONSUMPTION AND USES

Total domestic consumption of vanadium, as reported for all end-use categories in table 6, rose almost 9% in 1972. The marked increase in consumption in alloy steels and the decrease in consumption in carbon steel reflected a change in reporting. The old category for alloy steel (excluding stainless and tool) was subdivided into the following new categories: full alloy steel, high-strength low-alloy steel, and electric steel (special steel for use in electrical equipment). Under the revised reporting, some material that formerly appeared in the categories for carbon steel or miscellaneous and unspecified now appears in the new alloy steel categories.

Union Carbide Corp. announced a new steel additive, trademarked Nitrovan, containing 78% to 80% Vanadium, 6% to 7% nitrogen, and 10% to 12% carbon. It was designed for use in vanadium-nitrogen high-strength steels, especially the "killed" grades. Nitrovan was said to have the advantages of dissolving quickly and mixing uniformly in the steel, and having a higher purity than the premium grades of ferrovanadium.

Table 5.—Consumption and consumer stocks of vanadium materials in the United States

(Short tons of contained vanadium)

[2] Includes pigments.

STOCKS

In addition to the consumers' stocks reported in table 5, producers' stocks of vanadium as fused oxide, precipitated oxide, metavanadate, metal, alloys, and chemicals totaled 3,640 short tons of contained vanadium at yearend 1972, compared with 3,775 tons at yearend 1971.

PRICES

The dealer price quoted by Metals Week for export merchant technical-grade vanadium pentoxide remained at the late 1971 level of $1.50 per pound of contained V_2O_5 throughout the whole of 1972. The quote for domestic 98% fused vanadium pentoxide, applying to metallurgical markets, also was unchanged at $1.50 per pound of contained V_2O_5. The price for technical-grade, air-dried vanadium pentoxide, used by the chemical industry, stayed at $2.21 per pound of contained V_2O_5, f.o.b. plant, from 1971 through the end of 1972.

GSA sold all its excess vanadium pentoxide in May for bids ranging between $1.14 and $1.18 per pound of contained vanadium pentoxide.

There were small changes in some of the ferrovanadium prices in 1972. The price for U.S. standard grade ferrovanadium was $4.12 per pound of contained vanadium f.o.b. shipping point until July 1, when it rose to $4.19 for the rest of the year. On July 1 the price of Carvan also rose, in this instance from the $3.48 per pound of contained vanadium that existed since 1971 to the $3.66 that continued through the end of 1972. The price for Ferovan remained unchanged during 1972 at $3.68 per pound of contained vanadium.

FOREIGN TRADE

During 1972 exports of both ferrovanadium and vanadium ores, concentrates, and oxides varied irregularly from month to month, usually at a low level. The declared value for exports of ores, concentrates, and technical-grade oxides averaged

$1.21 per pound of contained vanadium pentoxide in 1972, compared with $1.98 in 1971. The declared value for exports of ferrovanadium averaged $2.34 per pound of alloy, compared with $2.58 in 1971.

No imports classified as vanadium ore and concentrate were received in 1972. Imports of vanadium-bearing materials such as ashes and slags, which are classified as metal-bearing residues, were estimated to be about 2.8 million pounds of contained vanadium in 1972, compared with 4.0 million pounds in 1971. Most of these materials originated in the Republic of South Africa and Chile.

WORLD REVIEW

Besides those listed in table 9, several other nations produced relatively minor amounts of vanadium, usually from secondary, waste, or byproduct sources. Japan and Canada both produced vanadium from several such sources, as did West Germany. While the world market for vanadium was not strong in 1972, it was better than in 1971.

Australia.—The Julia Creek, Queensland, vanadiferous oil shale project was expected to be set back because of technical problems relating to vanadium extraction. A special research program to solve these problems was anticipated to take at least 2 years. The project is a joint venture of the Oil Shale Corp., Australian Aquitaine Petroleum, and Pacminex Pty.[2]

Ferrovanadium Corp. N.L. announced the discovery of gold in its vanadium-bearing titanomagnetite-titanomartite ore body. Later in the year, it announced that it had commissioned a leading engineering group to make a feasibility study of the deposit.

Finland.—Rautaruukki Oy, Finland's vanadium producer, revealed plans for opening a new mine and vanadium pentoxide operation at Mustavaara, 125 miles north of their present source of vanadium at Otanmäki. The operation was designed to produce about 1,850 short tons of contained vanadium annually from 1.76 million tons of ore. The deposit was estimated to contain 44 million tons of ore, and is to be mined as an open pit.

France.—According to French trade statistics, France imported 855 short tons of vanadium pentoxide (not including other vanadium oxides) in 1971, of which 476 tons came from Finland, 171 tons from West Germany, 138 tons from the Netherlands, and the balance from other sources. The camparable import figure for 1970 was 1,483 short tons, of which 622 tons came from West Germany, 410 tons from

---

[2] Metal Bulletin (London). Julia Creek Setback. No. 5729, Sept. 1, 1972, p. 18.

Finland, 396 tons from the Netherlands, and the balance from other sources.

Germany, West.—According to the trade statistics of West Germany, imports of vanadium-bearing slags and residues totaled 33,800 short tons (gross weight) in 1972, 5,720 tons of this from Belgium-Luxembourg, 1,835 tons from France, 1,050 tons from the Soviet Union, 415 tons from other European and Israeli sources, and the balance from unspecified sources. For comparison, the imports of vanadium-bearing slags and residues totaled 24,240 short tons in 1971, 3,800 tons of this from Belgium-Luxembourg, 1,350 tons from France, 840 tons from other European and Israeli sources, and the balance from unspecified sources.

Luxembourg.—Continental Alloys began installing slag roasting facilities at its works at Dommeldange and hoped to begin operation some time during 1973. The plant was designed to have a capacity of about 2,000 tons of fused flake vanadium pentoxide product per year, and to consume South African vanadiferous slag barged to the plant by way of the inland waterway system. Already existing facilities at the same location will convert the fused flake product into ferrovanadium.[3]

Mozambique.—The Cia. do Urânio de Moçambique has submitted a feasibility study for a vanadium slag-producing iron and steel works to the Portuguese Government. The proposed plant would be built in the Tete district by mid-1975 and would use local vanadium-bearing titanomagnetite ore and coal, while electricity would come from the Cabora Bassa power complex now under construction. The process route would involve electric reduction and LD steelmaking.[4]

South Africa, Republic of.—The vanadium-bearing slag output of Highveld Steel and Vanadium Corp., Ltd., totaled 31,072 short tons in the fiscal year ending June 30, 1972, compared to 31,736 short tons in the previous fiscal year. Although the gross weight declined, the actual output of vanadium pentoxide in the slag was the highest to date because of an increase in the proportion of vanadium in the iron. The problem with electrode failure in the iron furnaces was solved, so that the plant was able to operate at 95% of rated capacity after the end of February. The fifth prereduction kiln was commissioned on schedule in February 1972.

The company's Vantra Division produced vanadium pentoxide at a substantially lower rate in this fiscal year than last year because of the poor market for vanadium. Because of this reduced production, the Vantra Division began using ore from the Mapochs mine in April 1972, resulting in the temporary closure of the Kennedy's Vale mine and in the indefinite postponement of operations in the new Northam mine.

United Kingdom.—Imports of ferrovanadium were 197 tons (gross weight) in 1971, with 137 tons coming from Austria

and the balance from three other sources. These imports were only a fraction of the 1970 total of 1,308 tons, 524 tons of which came from Austria, 216 tons from Norway, 195 tons from Sweden, and the balance from six other sources.

TECHNOLOGY

As in the last several years, much of the research on vanadium in 1972 centered on vanadium metal as a possible structural material for fast-breeder reactors, and on vanadium extraction from raw materials. There was an investigation of the purification of vanadium metal by an electrotransport technique. A pair of studies were made which have implications concerning the strength of vanadium metal, specifically concerning allotropy in vanadium and deformation mechanisms of vanadium. Three investigations were reported concerning carbon, nitrogen, and oxygen impurities in vanadium metal, and two interesting new processes for extracting vanadium were patented.

Electrotransport was demonstrated to be an effective method of reducing interstitial impurities in vanadium metal to a total amount less than 5 weight ppm.[5] The technique of electrotransport involves heating a cylindrical rod by internal electrical resistance to cause migration of the impurities towards the cathode end upon application of a high density electric current.

Both polycrystalline and single crystal vanadium metal were strained in tension at low temperatures, varying both the strain and the temperature, to study the deformation mechanism. A change of rate-controlling mechanism occurred at approximately 200 K. The predominant controlling mechanism seemed to be the interaction between dislocations and interstitial impurities at temperatures between 200 and 293 K. Single crystals developed mechanical twins when deformed at 77 and 120 K.[6]

The possibility of allotropy in vanadium at subambient temperatures was investigated by measuring electrical resistivity and elastic constants, and by X-ray diffractometry. While some previous workers have proposed a low-temperature allotropic form on the basis of anomalies in various properties, no evidence of allotropy was found in the temperature range 77 to 300 K.[7]

Using transmission electron microscopy on thin foils doped with carbon, the precipitation of carbon from a supersaturated solid solution in vanadium was investigated. It was found to precipitate initially as a finely dispersed carbide which became coarser with age.[8] The precipitation rate must largely depend on the rate of carbon diffusion.[9]

Other investigations disclosed that the precipation of $V_{16}N$ occurs homogeneously in vanadium-nitrogen alloys but requires long-range diffusion of nitrogen,[10] and, contrary to the conclusions of some investigators, the scavenging action of titanium for oxygen in vanadium-titanium alloys is apparently not a function of titanium concentration.[11]

One of the new processes patented in 1972 involved the extraction of vanadium from calcium-containing vanadium ore. Vanadium can be extracted from high-calcium ores and oil shales by slurrying the calcined ore in highly alkaline water, treating the slurry with carbon monoxide to precipitate waste calcium carbonate, contacting the vanadium-enriched solution with a basic anion exchange resin, and then stripping the adsorbed vanadium from the resin with a sodium chloride solution.[12] Another patent provided for vanadium recovery from ore leach solutions or other aqueous acidic solutions by contacting the solution with a specified fluorinated beta-diketone dissolved in kerosene or isooctane, and then stripping the vanadium-rich organic phase with a strong mineral acid.[13]

Vermiculite

By Frank B. Fulkerson [1]

Crude vermiculite production increased 12% in 1972. The vermiculite was shipped from Montana and South Carolina mines to processing plants in 31 States for exfoliation. Apparent consumption of exfoliated vermiculite increased 18%. The exfoliated material was used mainly as lightweight concrete aggregate, as loose fill insulation, and in horticulture. Output of crude vermiculite in the Republic of South Africa, the only other significant world producer, advanced 12%.

DOMESTIC PRODUCTION

Crude Vermiculite.—The quantity of crude vermiculite sold or used by producers increased from 301,000 tons in 1971 to 337,000 tons in 1972. The principal producer was the Construction Products Division, W. R. Grace & Co., which operated mines near Libby, Mont., and Enoree, S.C. The only other producer was Patterson Vermiculite Co., Lanford, S.C.

W. R. Grace & Co., continued construction on a $7 million, 1,000-ton-per-day wet-processing plant near Libby. The new facility, scheduled to be completed in mid-1973, was being equipped to process finer sized ores.

Exfoliated Vermiculite.—The tonnage of exfoliated vermiculite sold or used by producers increased from 209,000 in 1971 to 247,000 in 1972. The lightweight material was produced at 50 plants in 31 States. Leading producer was W. R. Grace & Co., which operated 26 plants in 22 States. Leading States were California, Florida, New Jersey, South Carolina, and Texas. About 42% of the exfoliated vermiculite was produced in the five States.

CONSUMPTION AND USES

Lightweight concrete aggregate, loose fill insulation, and horticulture were the principal markets for exfoliated vermiculite. The quantity used as lightweight concrete aggregate increased from 74,400 tons in 1971 to 80,000 tons in 1972, and the quantity consumed as loose fill insulation advanced from 71,200 tons to 74,000 tons. The tonnage consumed in horticulture increased from 28,000 to 40,000.

By main categories, the end-use pattern was as follows: Aggregates (concrete, plaster, cement), 42%; insulation (loose fill, block, pipe covering, packing), 34%; agriculture (horticulture, soil conditioning, fertilizer carrier, litter), 21%; and miscellaneous, 3%.

PRICES

The Engineering and Mining Journal quoted yearend prices for crude vermiculite as follows: Per short ton, f.o.b. mine, Montana and South Carolina, $25 to $38; and c.i.f. Atlantic ports, Republic of South Africa ore, $35 to $49.

The average value of crude vermiculite, screened and cleaned, at the mine, was $24.01 per short ton, compared with $23.91 in 1971. The average value of exfoliated vermiculite was $100.31 per short ton, compared with $99.93 in 1971.

FOREIGN TRADE

Quantities of crude vermiculite were exported to Canada and other countries, but tonnage figures were not available. The Republic of South Africa was the only important source of vermiculite imports. The crude vermiculite was imported duty free into the United States.

WORLD REVIEW

The United States and the Republic of South Africa produced nearly all the vermiculite used in the free world. Some vermiculite was probably produced in the U.S.S.R., but data were not available.

Early in 1972 Palabora Mining Co. completed the expansion and modernization of its dry-processing plant in northeastern Transvaal, Republic of South Africa. Mill capacity was increased from 140,000 tons per year to 175,000. Total cost of the mill modifications, including a dust collection system, was $3.5 million. The new plant gave the company the capability to process finer sized ore grades. This increased available ore reserves 50%. Demand for the finer sizes was increasing. Palabora produced a record 163,000 short tons of crude vermiculite in 1972. The year's output was about 17,000 tons higher than that of 1971. Most of the vermiculite was exported to Europe; some was also shipped to North America, Oceania and the Far East. A new subsidiary, Micronized Products, Ltd., was formed to market exfoliated vermiculite in the filter-aid and related fields.

TECHNOLOGY

A patent was issued on the use of exfoliated vermiculite in the thermal insulation of a steam injection well. The annular space between two strings of casing in the well is filled with a slurry of exfoliated vermiculite.[2]

A process was patented for the use of vermiculite in waste water treatment. Vermiculite ore is chemically exfoliated with aqueous n-butylammonium chloride, sodium chloride, or lithium chloride to produce a bulk material having enhanced absorptive and coagulative properties for removing contaminants from waste water.[3]

A patent on the use of vermiculite to remove oil spills from the surface of oceans, lakes, and rivers was issued. To remove the oil from the water surface, a wicking composition consisting of asphalt-treated or otherwise hydrophobized exfoliated vermiculite is spread on the water, the oil is absorbed in the wicking material, and the loaded material is burned.[4]

An improved production method for exfoliating vermiculite and simultaneously incorporating fertilizer values into the exfoliated material was patented. The ore is preheated in a saturated atmosphere to maintain its water content prior to thermal expansion, and the preheated ore is mixed with a molten mass of the fertilizer salts. The ore is exfoliated by the heat of the molten mass, resulting in a semisolid, very pliable and workable mass. The mass is cooled, and the cooled material is ground.[5]

A West German patent was granted on the preparation of exfoliated vermiculite having ion-exchange properties, high water absorption, and good insulation characteristics. Sized crude ore is exfoliated by irradiation with electromagnetic waves. Preferably, the ore is activated before heating by incorporating added cations such as nitrogen, sulfur, or oxygen.[6]

Zinc

By Albert D. McMahon,[1] John M. Hague,[2] and Herbert R. Babitzke[1]

The producing segments of the domestic zinc industry operated at low levels in 1972, but the use of zinc almost reached the record high of 1966. A large number of small and intermittent producing mines active in 1971 were idle in 1972, and several significant operations closed, which resulted in an annual production loss of 24,000 short tons. The number of mines reporting zinc production to the Bureau of Mines declined from 214 in 1970 to 142 in 1971 and 68 in 1972. The new zinc-copper mine in Maine, byproduct zinc from the Brushy Creek mine in Missouri, and the coming expansion of the Balmat mine in New York should reverse the decline in U.S. mine production of recent years. The closure of a slab-zinc-producing plant, the largest electrolytic zinc refinery in the United States, a 17% drop in zinc concentrate imports and decreased mine production were the principal reasons for the 140,000 ton decline in smelter production during 1972. This loss of supply was partially replaced by releases of slab zinc from the national stockpile authorized by Public Law 92–283. Substantial increases in demand for most all use categories were in response to greater industrial activity in 1972. The automotive, construction, and appliance industries, the major consumers of zinc for diecastings, galvanizing, and brass and bronze products all improved over 1971. Demand followed the seasonal pattern, increasing each month to a high in May, receding during the vacation months of June and July, rising again to a peak for the year in October, then declining for the last 2 months. Record quantities were used: Galvanizing reached a record high; 1972 was the third largest year for zinc diecastings; and for brass products, 1972 was surpassed only by the World War II years, 1941 through 1945.

General Services Administration (GSA) sales of zinc during the first 3 months of 1972 depleted the balance authorized under Public Law 89–322. New legislation for the release of an additional 515,200 tons became law in the latter part of April after negotiations between GSA and primary producers developed an agreeable disposal plan. Approximately 190,000 tons were committed from May through December. Revisions of the disposal plan will allow depletion of the balance by the end of the first quarter of 1974.

Total imports (zinc in concentrates plus metal) increased to 777,500 tons, 17% higher than those of 1971: The zinc content of imported concentrates declined 26% and imports of metal totaling 522,600 tons were up 64%.

Throughout 1972 the price of domestically produced Prime Western zinc was controlled by the Price Commission. It allowed increases of 1 cent and 1/2 cent per pound in April–May and December respectively, raising the ceiling price to 18.5 cents per pound. Foreign zinc sold in the United States commanded at least a 1 cent premium as Australian, Canadian, Mexican, and Peruvian producers increased the price of their zinc in the United States some time prior to the raises allowed U.S. producers by the Price Commission.

Legislation and Government Programs.—The GSA sold 20,580 tons of zinc during the first quarter of 1972. This zinc was all that remained under the authorization of Public Law 89–322 enacted November 4, 1965, for disposal of 200,000 tons of zinc from the national stockpile. On April 26, 1972, the President signed Public Law 92–283 authorizing release of approximately 515,000 short tons of zinc over a period of years of which 440,000 tons was to be released through primary domestic producers and 75,000 tons was for sale by

---

[2] Mining engineer, Division of Nonferrous Metals.

GSA on an off-the-shelf basis. This zinc was in excess to stockpile requirements, and all zinc released was for domestic consumption only. The inventory up to objective is 560,000 tons. Sales under Public Law 92–283 through December 31, 1972, were 190,668 tons: 128,450 tons to primary domestic producers and 62,218 tons as shelf item sales. As a result of the rapid drawdown of the 75,000 tons off-the-shelf zinc, release under the program was temporarily suspended on December 18, 1972, and a revised program was issued January 15, 1973. The revised program offered 6,400 tons of zinc each calendar quarter through June 1973, followed by 6,250 tons per quarter as long as zinc remained available for sale to domestic primary producers under their long-term agreements with GSA. The set-aside program was revised upward effective July 1, 1973, to allow releases of 25,000 tons of zinc to domestic consumers per quarter and at the same time allowing producers to draw more zinc from the stockpile. On December 31, 1972, approximately 313,552 tons of zinc remained to be released through primary domestic producers, and 12,782 tons remained from the original 75,000 tons set-aside for off-the-shelf sales. No transfers of zinc to Government agencies were made in 1972, leaving a balance of 22,097 tons of the 50,000 tons approved in Public Law 89–9 passed April 2, 1965.

During the year producers remelted 75,840 tons of GSA zinc, and 37,806 tons was purchased for direct shipment to customers without altering its form, an additional 62,218 tons was released off-the-shelf directly from GSA to consumers, and 20,580 tons was sold under Public Law 89–322 resulting in a total of 196,444 tons. However, the GSA stockpile report to the Congress shows a decrease of 188,354 tons in the physical inventory of zinc during the year which reflects nondelivery of some orders, therefore it may be concluded that 188,354 tons of stockpile zinc entered the zinc supply during 1972.

The President's economic stabilization program, which entered Phase 2 November 12, 1971, continued through 1972. The program made it mandatory for domestic zinc producers to justify to the Price Commission price increases in their products. A criteria of cost justification and a profit

margin test was used to determine if a price increase was warranted.

The International Lead and Zinc Study Group held its 16th annual meeting in Geneva, Switzerland, November 16, 1972. Meetings of various committees and subcommittees were held before and during the session. The 1972 forecasts made at the 15th annual meeting for world zinc mine and metal production were reduced to estimates of 4,810,000 short tons and 4,540,000 tons, respectively. The zinc metal consumption forecast was increased to an estimated 4,788,000 tons. Forecasts for 1973 showed substantial increases in mine and metal consumption. Other topics discussed were research and development, long-term projections, consumption trends, trade liberalization, new mine and smelter projects, and scrap.

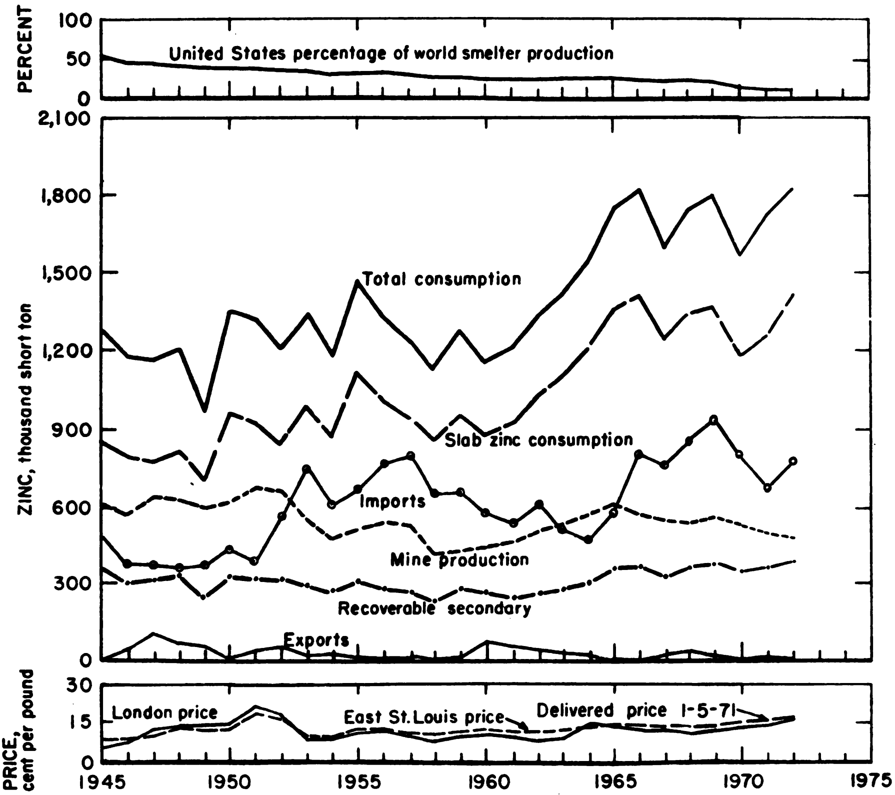

Figure 1.—Trends in the zinc industry in the United States.

DOMESTIC PRODUCTION

MINE PRODUCTION

Mine production of recoverable zinc in the United States declined 5% in 1972 to 478,318 tons, the lowest annual output since 1961. Production was reported in 18 States. Five States recorded increases over 1971, and 13 States recorded decreases. Tennessee led the Nation in zinc production for the 15th consecutive year with 101,722 short tons, 15% below that of 1971. Colorado ranked second with a 4% increase, Missouri ranked third with a 28% increase, and New York ranked fourth with a 4% decrease from 1971. Nevada mine production dropped to zero and Montana dropped to 12 tons for 1972. The States east of the Mississippi River accounted for 55% of the U.S. 1972 mine production.

Sources of zinc production for 1972 are

shown in table 4 according to the principal metal or combination of metals extracted. The percentage distribution is as follows: Zinc ore, 57%; zinc-lead ores, 21%; lead ores, 14%; copper-zinc and copper-lead-zinc ores, 6%; and from all other sources, 2%. Less high grade zinc ore was mined in 1972, but there was a net increase in the zinc content over that of 1971. The average zinc content of the 6.5 million tons of zinc ore mined in 1972 was 4.23% (274,440 tons of zinc) compared with 6.8 million tons of ore averaging 3.74% zinc (256,247 tons of zinc) in 1971.

The 25 leading mines listed in table 5 accounted for 89% of the domestic recoverable mine production. The five leading mines produced 36%, and the first 10 mined 56%.

Tennessee maintained its rank as the leading producing State in 1972. Production from mines of the American Smelting & Refining Co. (ASARCO) continued as planned in 1972 and amounted to 75,200 tons of zinc. The Coy mine, the smallest of the four operating units, was shutdown in August to start a development program that will increase production capacity.[3] The Mascot mill, which has operated since 1913, will be replaced by a new one with 20% more capacity. The new mill, scheduled for completion by mid–1974 at a cost of $6.3 million, will be built at the Young mine site and will process ores from the Young, Coy, and Immel mines. Ore from the New Market mine was processed at the New Market mill. Zinc reserves at ASARCO's Tennessee mines have been estimated in excess of 77 million tons of ore averaging 3% to 4% zinc. Two valuable mill byproducts from the Mascot and the Young concentrators are marketed by ASARCO's American Limestone Co. Tailings are used for agricultural limestone, and the sink-float reject is sold as crushed stone.[4]

The New Jersey Zinc Co. closed the Flat Gap mine October 1, 1972. Operations at Flat Gap began in 1959, and except for 3 years, it was one of the 25 largest U.S. producers every year including 1972. The Jefferson City mine of The New Jersey Zinc Co. and the Zinc Mine Works of U.S. Steel Corp. in east Tennessee operated throughout the year. Work is underway to develop a mine and mill at Elmwood in central Tennessee.[5] Occidental Minerals Corp. (Oxymin), a subsidiary of Occidental Petroleum Corp., continued evaluation of its central Tennessee discovery and leased additional acreage in this area. Development of this property was under discussion with a major mining company.[6]

Mine production in New York, all from the Balmat-Edwards Division mines of St. Joe Minerals Corp., was 4% lower than in 1971. Output is expected to increase from 63,500 tons in 1972 to 100,000 tons in 1973.[7]

Production in New Jersey, Pennsylvania, and Virginia by The New Jersey Zinc Co. was 1,000 tons, or 1.4% below that of 1971. A mining method change instituted at the Sterling mine at Ogdensburg, N.J., increased output substantially. Operation at the Friedensville mine at Center Valley, Pa., for a long time the company's highest profit producer, were seriously affected by ground subsidence problems and flooding caused by Hurricane Agnes.[8]

In Colorado, mine output increased 4% in 1972 to almost 64,000 tons and another record. New Jersey Zinc Co.'s Eagle mine produced the largest tonnage of zinc, although somewhat less than last year. The Resurrection mine, a joint venture owned equally by Resurrection Mining Co. (a 100% owned subsidiary of Newmont Mining Corp.) and ASARCO, was next and operated continuously during 1972. Ore milled during 1972 averaged 7.6% zinc, 3.9% lead, and 2.4 ounces of silver per ton. Rated mill capacity of 700 tons of ore per day was not maintained consistently during 1972, but additional production from the recently opened No. 5 ore body should bring it up to near capacity during 1973. Ore reserves as of January 1, 1973 were estimated at 2,609,500 tons averaging 9.92% zinc, 5.16% lead, and 2.53 ounces of silver and 0.068 ounce of gold per ton.[9] Newmont Mining Corp.'s Idarado mine was Colorado's third largest producer and the Sunnyside mine of Standard Metals Corp. ranked fourth. At the Idarado mine, development during 1972 resulted in additions to ore reserves exceeding the tonnage mined and milled. Ore reserves at the end of 1972 were 2,865,000 tons averaging 4.80% zinc, 3.31% lead, 0.74% copper, and 0.03 ounce of gold and 1.75 ounces of silver per ton. Labor continues to be in short supply, but training programs during the year helped to increase the Company's mining efficiency.[10]

[9] Newmont Mining Corp. 1972 Annual Report. Pp. 9–10.

Mine production of zinc in Maine at 5,820 tons, was approximately the same as in 1971. Callahan Mining Corp.'s Penobscot mining and milling operations ended in July 1972 because ore reserves were exhausted. Funds set aside by the Callahan Mining Corp. were used to restore the area in a manner considered desirable by a committee of local and State representatives in cooperation with Federal agencies. In 1967, Callahan Mining Corp., The Superior Oil Co., and The New Jersey Zinc Co. joined in a program of primary exploration in Maine and adjacent areas that has proven encouraging. Two properties are scheduled for testing by drilling in 1973, and several others are in earlier stages of examination.[11] Kerramerican, Inc., a U.S. subsidiary of the Canadian company Kerr Addison Mines Ltd., has 60% interest in the Blue Hill mine at Blue Hill, Maine, after financing it to production at a cost of $6.3 million. The other 40% being retained by Black Hawk Mining Ltd., the company that did extensive development work at the mine in the 1960's. Production started October 4, 1972, and during the last quarter 53,000 tons of ore averaging 0.56% copper and 9.90% zinc were milled to 186 tons of copper and 4,500 tons of zinc in separate concentrates. All ore milled resulted from development work. The mill treated an average of 950 tons of ore per day 5 days per week because mine development was behind schedule owing to inexperienced miners and the structural complexity of the ore. Ore reserves as of December 31, 1972, including an allowance for dilution, were estimated as follows: Main Zone—zinc ore 682,000 tons (14.0% zinc and 0.4% copper), zinc-copper ore 223,000 tons (9.4% zinc and 1.4% copper), Mammoth Zone—zinc ore 147,000 tons (15.9% zinc and 1.1% copper), copper ore 366,000 tons (2.1% copper and 1.2% zinc), L.S.P. Zone—copper ore 150,000 tons (2.2% copper). Exploratory surface diamond drilling was resumed late in the year.[12]

Missouri moved up to third place among the zinc producing States with an increase in mine production of 28% for 1972. By-product zinc production by St. Joe Minerals Corp., Southeast Mining and Milling Division, was 5% lower than in 1971. The Buick mine-mill-smelter complex owned by American Metal Climax, Inc. (AMAX) and Homestake Mining Co. increased production as a result of mining a larger tonnage of higher grade ore. During 1972 about 1,447,000 tons of ore was mined and milled, and 189,000 tons of lead concentrate and 82,000 tons of zinc concentrate were produced. The zinc concentrate was shipped to AMAX's zinc smelter at Blackwell, Okla., for treatment.[13]

Byproduct zinc output by the Ozark Lead Co. in 1972 was slightly lower than in 1971 although production of lead in concentrate increased 25%. The Magmont mine at Bixby, Mo., operated by Cominco American Inc., a joint venture of Cominco Ltd. and Dresser Industries, Inc., produced 1,034,000 tons of ore averaging 7.9% combined lead and zinc compared with 1,040,000 tons of ore with 8.5% in 1971.[14]

Mine production of zinc in Idaho for 1972 declined 14% to 38,600 tons. The Bunker Hill mine operated by the Bunker Hill Co., a subsidiary of Gulf Resources & Chemical Corp., produced slightly more ore in 1972, but the average grade of zinc declined. Mining from the zinc ore zones in the upper levels using "blast hole stoping" began at a satisfactory rate in the latter part of the year. Greater efficiency results when this method can be used to mine large blocks of ore. Exploration and mine development work will be resumed and accelerated after improvement projects have been completed.[15] The Star-Morning mine, 70% owned by the Bunker Hill Co. and 30% by Hecla Mining Co., produced 263,595 tons of ore containing 7.36% zinc in 1972, compared with 246,053 tons with 6.72% zinc in 1971. Extensive development was completed in 1972 including sinking the No. 4 shaft to the 7,900-foot level, 2,000 feet of new openings on the 7,500-foot level, 2,500 feet of development of veins other than the main vein and 650 feet of cross cutting on the 1,700-foot level.[16] Independent contractors operated the Gray Rock section of the Monitor mine, owned by Day Mines Inc. They produced and milled 20,259 tons of ore averaging 8.90% zinc, 2.80% lead, and 1.15 ounces silver per ton. Ore reserves at the end of the year were adequate for 2 years of operation at the present rate of production.[17]

[15] Gulf Resources & Chemical Corp. 1972 Annual Report. P. 24.

Utah's mine output of zinc was 15% lower in 1972 than in 1971. The Mayflower mine, leased by the Hecla Mining Co. from New Park Resources, Inc., in 1961, was closed on December 31, 1972, and the agreement was terminated. Production in 1972 totaled 114,604 tons of ore containing 0.96 ounce of gold and 5.95 ounces of silver per ton, 3.22% lead, 2.01% zinc, and 1.35% copper, compared with 124,354 tons assaying 0.51 ounce of gold and 5.12 ounces of silver, 4.01% lead, 2.44% zinc, and 1.26% copper during 1971.[18] Production at Kennecott Copper Corp.'s Tintic Division was higher in 1972 than in 1971 owing to slightly improved working conditions and a new ore zone discovered east of the main Burgin ore zone. The critical shortage of skilled miners continued throughout the year, requiring the assignments of mine development on a priority basis.[19]

Mine production of zinc in Arizona increased 30% in 1972. Cyprus Mines Corp.'s wholly owned Bruce mine near Bagdad operated at near capacity and produced 10,600 tons of zinc and 3,400 tons of copper in concentrates from 96,211 tons of ore assaying 13.7% zinc and 3.92% copper. The shaft was sunk to 2,320 feet from where an inclined tunnel was driven in mineralization 95 feet below the shaft bottom. Ore has been developed between the 2,150- and 2,300-foot levels that will extend the life of the mine at least 1 year. Known reserves are sufficient for at least 5 years at the present operating rate.[20] In 1972, mine output of zinc in New Mexico declined 9% from that in 1971. At ASARCO's Ground Hog unit in New Mexico, mining began on ore bodies leased in 1971, which are an extension of the Ground Hog deposit.[21]

In Washington, 1972 zinc mine production increased 12% to almost 6,500 tons. Pend Oreille Mines and Metals Co. mined and milled 216,000 tons of ore and produced 11,000 tons of zinc concentrate. The decline to the "Yellowhead Formation" started during the last quarter was advanced 805 feet leaving 2,365 feet to the target area. Another decline produced 11,600 tons of ore from the Lower Dolomite in August and September.[22] Callahan Mining Corp.'s property near Colville, Wash., was tested and confirmed for amenability to low-cost underground mining methods. However, the grade of the deposits was lower than hoped to justify equipping for production. A partner will be sought to share the larger expenditure required to prove additionl tonnage.[23]

Wisconsin mine production of zinc decreased 35% in 1972 because of mine closures in 1971. A 10% reduction to 11,400 tons was registered for Illinois in 1972.

SMELTER AND REFINERY PRODUCTION

U.S. slab zinc production at smelters and electrolytic plants declined 17% from last year to 706,898 short tons in 1972. The decline reflected the closure of four plants in 1971 and one in 1972, and decreased domestic mine production and imports of zinc concentrate. Monthly data published by the Zinc Institute, Inc., showed a decline in production through the year with a low in September and December. Average monthly primary smelter production was 20% less in the last 6 months compared with the first 6 months of 1972. Shipments were lower throughout the year even with the inclusion of GSA stockpile zinc and a drawdown in producers' stocks. Producers' stocks declined 37% from 50,589 tons to 31,775 tons during the year. In addition to slab zinc production, producers purchased 113,646 tons of GSA stockpile zinc during the year; they shipped 37,806 tons directly to customers and remelted 75,840 tons for upgrading.

The closure of The Anaconda Company's Great Falls, Mont., electrolytic plant on August 4, 1972, decreased the Nation's annual production capacity for zinc by 163,000 tons to 721,500. Another closure was announced for the horizontal retort smelter at Blackwell, Okla., at the end of 1973 reducing total capacity to 649,500 tons.

Refined zinc production at primary smelters and electrolytic refineries was derived from the following: Domestic ore, 57%; foreign ore, 33%; and scrap, 10%. The quantity of slab zinc produced from domestic ore in 1972 was slightly less than in 1971 but that from foreign ore and scrap decreased 36% and 9%, respectively. Primary refined zinc produced at electrolytic plants was 19% lower than in 1971 and accounted for 37% of the total slab zinc produced; smelter production (distilled) was down 16% and made up 53% of the total. Redistilled secondary slab zinc produced from scrap by primary smelters declined 8% and contributed 9% of the total; the decrease from secondary smelters was 13% for 1.5% of the total. Production of all grades of zinc declined except for an 8% increase for Brass Special. Distribution of the total by grades was as follows: Special High, 44%; High, 6%; Intermediate, 6%; Brass Special, 11%; and Prime Western, 33%.

During 1972 ASARCO at Corpus Christi, Tex., completed installation of a new Lurgi fluid-bed roaster and a $3.2 million water treatment plant that can handle both normal plant effluent and rainwater runoff. Other projects to complete the modernization program and increase plant capacity by 15% were being studied.[24] The ASARCO horizontal retort zinc smelter had operated since mid-1969 in accordance with a variance issued and renewed periodically by the Texas Air Control Board (TACB). Several studies conducted by a consulting firm and the company resulted in the same conclusion confirming the company's inability to meet the costs of the extended control facilities required to comply with TACB regulations. At one TACB hearing ASARCO urged the Board to permit the plant to be operated until mid-1975. At two subsequent hearings TACB voted to require the smelter to be in compliance with the States' air quality standards by December 31, 1973. However, at the hearing on July 26, 1973, ASARCO successfully appealed that decision and the Board voted (six to two) to allow the smelter to operate until May 31, 1975.[25]

AMAX exercised its option to purchase the American Zinc Co. electrolytic zinc plant at Sauget, Ill., in June for $3 million. AMAX will spend $19.4 million on plant improvements, process changes, and environmental protection systems.[26] The plant was scheduled to start up in the second quarter of 1973 and is expected to reach full capacity of 84,000 tons of Special High grade zinc annually by 1975. This production will be accompanied by 1.35 million pounds of byproduct cadmium and 150,000 tons of sulfuric acid.[27] AMAX announced in May the phasing out of the horizontal retort smelter at Blackwell, Okla., by the last quarter of 1973. This decision resulted from a determination that the plant could not compete profitably with the more modern electrolytic units.[28] The age of the plant and the nature of the process also render it obsolete in terms of current air quality standards.[29]

St. Joe Minerals Corp. produced 235,649 tons of zinc (zinc equivalent) in 1972 just slightly more than in 1971. Installation of a new sulfuric acid plant held back a larger output which should increase significantly in the future. A 40,000-ton expansion was scheduled for the next 3 years. Production of zinc oxide increased and shipments rose 46% due to the strong demand by the rubber and paint industries. The State of Pennsylvania requires St. Joe to recover in excess of 98% of the input of sulfur, whereas the Environmental Protection Agency (EPA) guideline was 90%. The Monaca, Pa., smelter recovery has been better than that required by EPA over the years, but the cost of meeting Pennsylvania regulations was estimated at $10 million. The ability to install the necessary process control equipment by 1977 will depend on the success of research to be conducted in 1973–74.

The New Jersey Zinc Co. reported an increase of 33% in net sales in fiscal 1972 compared with fiscal year 1971. Operating income also increased 64%. Zinc metal production was down 10% from that of 1971, but pigment production was up 21%. Metal production for fiscal 1972 was 97,000 tons, and pigment production was 147,000 tons. Even though the Palmerton, Pa., smelter was operating at full capacity, the company had difficulty in meeting orders. Strong demands were also encountered for zinc oxide and zinc dust. To meet the demand, the company proposed to build a plant in Aubry, France, to manufacture a complete line of zinc oxide; the plant was scheduled to be in operation by mid-1973. In completing the phase out of the former operations at Depue, Ill., the company has leased its agriculture chemical facilities to the Mobil Oil Corp. The New Jersey Zinc Co. continued its use of a portion of the Depue zinc refinery to produce zinc dust pigment from zinc scrap.[30] The company has also announced that it was planning to expand its facilities at Palmerton.

The Bunker Hill Co. in Idaho produced 101,700 tons of zinc in 1972, 8.2% more than in 1971. Engineering commenced on a leach-electrowinning facility for the recovery of copper from matte, spiess, and residues from the lead and zinc plants. The new plant may come onstream in 1974. The material that will be processed at this plant was sold to other producers in the past. The operation of Bunker Hill was much improved in 1972 over that of 1971. During discussions between the company, the State of Idaho, and EPA regarding sulfur dioxide emissions and effluent treatment to the south fork of the Coeur d'Alene River, it was decided that Bunker Hill will be able to meet the State plan, but EPA has not promulgated final regulations for Northern Idaho and Eastern Washington area.[31] Company officials have also considered adding to its zinc-producing capacity.

National Zinc Co. was sold to investors from Bartlesville, Okla.; however, National Zinc continued to manage the inspection for the new owners. The company operated the Bartlesville plant since its inception in 1907. The plant has a horizontal retort smelter that produces over 50,000 tons of slab zinc per year. Plans were to convert the operation to an electrolytic plant during the next 2 years with the same capacity.

Secondary Zinc Smelters.—Zinc recovered from zinc-bearing scrap was 387,761 tons in 1972, an 8% increase over that of 1971. New scrap consisting of semimanufactured forms, primarily zinc- and copper-base alloys, accounted for 79% of the new and old scrap processed. When compared with 1971, increases in zinc recovery were realized for all categories of new scrap, and copper- and aluminum-base alloys in old scrap; but decreases were noted for zinc- and magnesium-base alloys. Most of the zinc recovered, 46%, was from brass and bronze followed by slab zinc, 23%; chemical products, 13%; and zinc dust, 10%.

Slag-Fuming Plants.—Slag fuming plants process hot and cold lead blast-furnace slags, which contain 7% to 15% zinc, to produce zinc oxide fume. The oxide is sent either to zinc smelters or electrolytic refineries for recovery of zinc, or it is sent to the consumers as zinc oxide. During the year three plants were operating:

ASARCO	El Paso, Tex.
ASARCO	East Helena, Mont.
The Bunker Hill Co	Kellogg, Idaho

The East Helena plant was purchased by ASARCO from The Anaconda Company during the year. The transfer took place on July 3, 1972.

Byproduct Sulfuric Acid.—In 1972, there were nine plants with facilities for roasting zinc sulfide concentrates. Seven plants were equipped with sulfuric acid producing units, one of which was solely a roasting operation producing calcine for processing to zinc oxide or zinc metal. Two horizontal retort smelters did not have sulfuric acid producing facilities. In 1972, production of byproduct sulfuric acid from the zinc plants and two lead smelters was 859,103 tons, compared with 971,946 tons in 1971.

Zinc Dust.—Production of zinc dust was 59,358 short tons in 1972, an increase of 18% over that of 1971. Zinc dust produced from distilled scrap metal accounted for 40,123 tons, 41% more than in 1971.

[30] Page 20 of work cited in footnote 5.
[31] Pages 24–25 of work cited in footnote 15.

CONSUMPTION AND USES

Consumption of slab zinc in the United States during 1972 was 1,418,349 tons, an increase of 13% over that of 1971. The zinc content of ore and concentrate used directly to make pigments and salts and in galvanizing was 118,305 tons (119,254 in 1971); and the zinc content of scrap processed to make alloys, zinc dust and salts totaled 292,099 tons, up 5% from 1971. The overall total was 1,828,753 tons, an increase of 11% over that of 1971.

Slab zinc consumption was reported by nearly 600 users in 1972. Galvanizing accounted for 36% of the total slab zinc consumed; brass products, 14%; diecasting alloys, 40%; other zinc-base alloys, 1%; rolled zinc, 3%; zinc oxide, 4%; and other uses, 2%. Nearly all the use categories showed gains over last year. Of the 164,290 tons net gain, 43,452 tons of the increase was used in galvanizing, 41,661 tons for brass products, 62,109 tons for diecasting alloys, 6,364 tons for rolled zinc, and 11,949 tons for zinc oxide. Losses were noted in other uses.

Distribution of slab zinc consumed in 1972, by grade, is as follows: Special High grade, 49% High grade, 10%; Intermediate, 2%; Brass Special, 9%; Prime Western, 30%; and Remelt less than 0.1%. Compared with 1971, consumption of all grades increased—Special High grade, 12%; High grade, 25%; Intermediate, 14%; Brass Special, 17%; Prime Western, 9%; and Remelt, 40%.

Slab zinc consumed by rolling mills in 1972 was 45,216 tons, a 16% increase over that of 1971. Production of rolled zinc products increased 18%, to 45,216 tons. Sheet and strip consumed 62%, and 30% was used for photoengraving plate. Imports doubled over last year to 485 tons, and exports increased 43%, to 2,419 tons. More than 40,000 tons of zinc was rerolled from scrap in 1972, and the total rolled was 86,980 tons, compared with 58,539 tons in 1971.

The leading consumers of slab zinc in 1972 by State were Ohio with 14% of the total, followed in order by Illinois with 13%, Pennsylvania 12%, Michigan 11%, Indiana 10%, and New York 8%. The industries using zinc in these six States accounted for 68% of the slab zinc consumed, which was the same percentage as the last 2 years. Michigan was first in the use of zinc for diecastings, Ohio was for galvanizing, and Connecticut for brass mill products.

ZINC PIGMENTS AND SALTS

Production.—Published data for zinc pigments and compounds include two major items, zinc oxide and zinc sulfate. Information for leaded zinc oxide and zinc chloride was withheld in 1971 and 1972 to keep individual company data confidential. Figure 2 shows the trends in leaded zinc oxide and zinc chloride shipments prior to 1971.

Production of zinc oxide in 1972 was 237,015 tons, a 10% gain over 1971 production. Shipments increased by a greater percentage, reducing stocks to a low level. Zinc sulfate production declined from 45,929 tons to 38,897 tons, and shipments declined by a still larger tonnage to 39,595 tons.

Zinc pigments and compounds were made from a variety of semiprocessed materials including zinc ore and concentrate, slab zinc, and scrap. Lead-free zinc oxide, the major product in the zinc pigments group, was obtained from three sources: 57% from ores or concentrates (American process), 27% from metal (French process), and 16% from secondary materials. The ores used to produce American-process zinc oxide were 82% domestic and 18% imported. The major part of zinc sulfate production, 62%, came from secondary materials. For both oxide and sulfate, the tonnage and percentage of imported concentrates used in 1972 decreased from those of 1971.

A major change in zinc oxide producers took place in 1972 as ASARCO purchased zinc oxide plants at Columbus, Ohio, and Hillsboro, Ill., formerly operated by the American Zinc Co.

Consumption and Uses.—Shipments of zinc oxide by industry usage indicated an increase of 8% for total shipments in 1972. Rubber continued to be the major consuming industry, taking 53% of the total of lead-free zinc oxide. Photocopying continued a growth trend and became the second largest use, having more than doubled in volume in the last 5 years. Zinc sulfate shipments declined partly as a result of a 35% reduction in agricultural use. Consumption of leaded zinc oxide was only a small part of total zinc compound use. Zinc chloride registered a modest increase in consumption in recent years.

Prices.—At the beginning of 1972, prices in effect since July 1, 1971 were as follows: American-process pigment-grade lead-free zinc oxide, 17.50 cents; French-process lead-free oxide, 18 cents; and electrophotographic, 20.25 cents. Increases on May 1, 1972, October 27, 1972, and December 25, 1972, raised these by yearend to the following: American-process, pigment-grade, lead-free oxide, 18.25 to 19 cents; French-process, 18.75 to 20.50 cents; electrophotographic, 21 cents. Prices at the end of the year varied in relation to quality, quantity, and locality where available. As of December 25, 1972, U.S.P.-grade was 1 cent higher than electrophotographic, at 22 cents, and activation grade, the lowest quality quoted, ranged from 15.75 cents to 17.50 cents. The price for leaded zinc oxide, 12%, ranged from 14.50 cents per pound in January to 15.75 cents in December 1972.

Foreign Trade.—Exports of zinc oxide decreased 8% from the record amount of 1971 to 6,172 tons in 1972, and exports of lithopone rebounded from the low point in 1971 to a normal level of over 1,300 tons in 1972. Destinations were widespread throughout the world. Imports of zinc pigments and compounds increased by 24% to a record 25,934 tons; zinc oxide was the major component and the major cause of the increase. Canada and Mexico were the

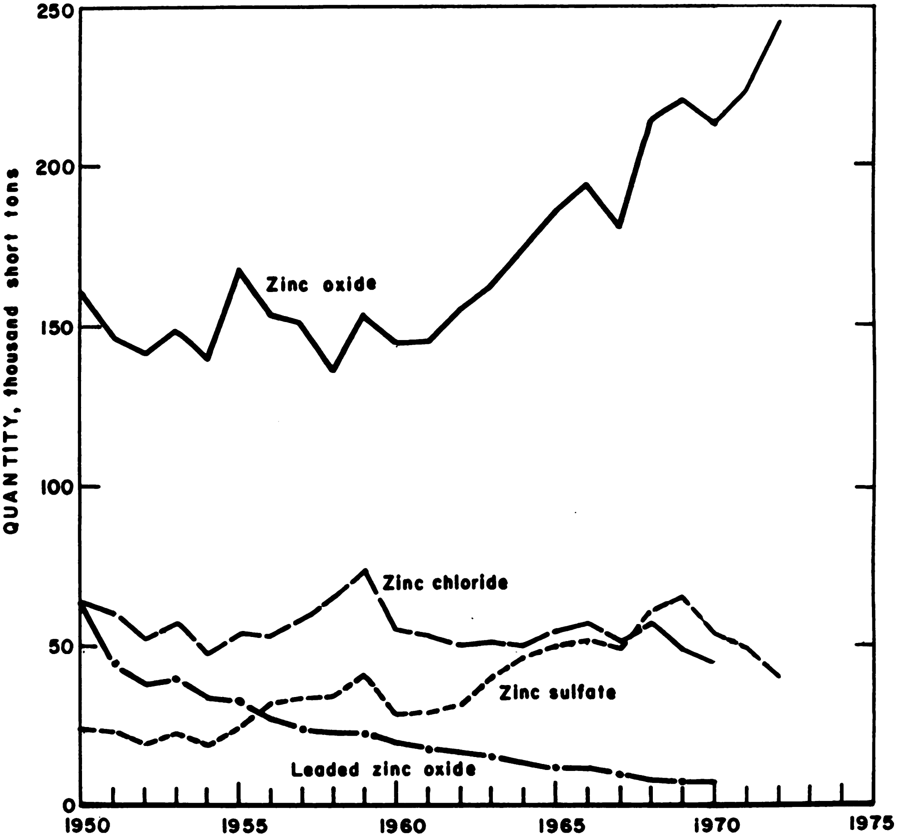

Figure 2.—Trends in shipments of zinc pigments.

principal sources, with minor contributions from the European Economic Community (EEC) countries. About one-fourth of the increase in demand for zinc oxide that developed during 1972 was satisfied by the increase in imported oxide.

STOCKS

Producer Stocks.—According to American Zinc Institute, Inc. data, stocks decreased until midyear to 21,221 tons at which time GSA stockpile zinc began to give some relief and producers stocks showed some gains, a trend that extended to the end of the year. The total decline in producer stocks for 1972 was 49%, the lowest year-end inventory since 1950. Stocks at secondary smelters gained continuously, with small fluctuations, ending 1972 with 1,225 tons, a threefold increase from yearend 1971.

Consumer Stocks.—Slab zinc inventories at consumer plants at the end of 1972 were 126,141 short tons, an increase of 38% over the ending stock for 1971. Prime Western grade accounted for the largest increase followed by Special High grade, Brass Special, and High grade.

Government Stockpile.—During 1972, the GSA stockpile inventory was reduced from 1,137,937 tons to 949,583 tons indicating that 188,354 tons of slab zinc went into domestic supply from the Government stockpile.

PRICES

The price of Prime Western zinc at the beginning of 1972 was 17 cents per pound; High grade and Special High grade prices were at 17.85 and 18 cents per pound, respectively. These prices remained unchanged since they were established July 26, 1971. A ceiling price of 17 cents per pound for Prime Western zinc was established August 16, 1971, by the President's Economic Policy during which time the Price Commission was established. In January 1972, St. Joe Minerals Corp. applied to the Price Commission for a 5.6% price increase in zinc; The New Jersey Zinc Co. applied in March. An increase was approved for St. Joe Minerals Corp. on March 16, 1972, at which time Prime Western zinc was sold at 18 cents per pound; High grade and Special High grade went to 18.85 and 19 cents per pound, respectively. At the same time ASARCO, The Bunker Hill Co., and AMAX withdrew from the zinc market. One by one the producers applied for price increases, which were granted one by one, and by May 12 all U.S. producers were in line with one domestic zinc price. Another round of price increases came in December with The New Jersey Zinc Co. being the first to receive approval from the Price Commission on December 20 to raise its price an average of 2.75% for all zinc products, bringing Prime Western to 18.5 cents, High grade to 19.35 cents, and Special High grade to 19.5 cents per pound. On December 21, St. Joe Minerals Corp. received permission for a price increase of 2.91%, which resulted in having this company's products bringing 18.52 cents per pound for Prime Western zinc, 18.78 for Continuous Galvanizing grade, 19.4 for High grade and 19.55 cents per pound for Special High grade. The above sequence of events led to a three-tier domestic market for zinc continuing to yearend. A number of requests that were made during the year to the Cost of Living Council to declare zinc an international commodity and free it from price control were rejected. On January 11, 1973, Phase 3 of the President's Economic Stabilization program took effect, at which time the Price Commission was phased out. Zinc prices began to increase with ASARCO taking the lead on January 18, 1973.

On March 6, 1972, Canadian producers boosted their price of zinc to 18 cents per pound (Prime Western equivalent). Within 1 week this move was followed by Australia and Peru. On April 27, and before the domestic zinc price was established at 18 cents per pound for Prime Western zinc, the foreign price was boosted to 19 cents per pound (Prime Western equivalent). This price remained until December 1 when an increase to 19.5 and 20 cents per pound came into effect for imported (Prime Western equivalent) zinc. A new grade of foreign zinc was introduced at the same time called Continuous Galvanizing grade (CGG) zinc at a price of 20.25 cents per pound. From December 1 to yearend there was a 2-cent spread between the ceiling price of domestically produced zinc and imported metal selling in the United States.

The average monthly London Metal Exchange price increased from the beginning of the year price of 17.21 cents to 17.99 cents per pound (U.S. equivalent) in March, after which it declined to 16.48 cents per pound in August. In November the average price advanced to 17.16 cents per pound, followed by a decline to 17.0 cents per pound in December. The general decline in price was a result of the decline in the sterling exchange rate. The European producer price quoted at £150 per metric ton (16.46 cents per pound U.S. equivalent in June 1971 and 17.78 cents per pound in May 1972) effective since June 17, 1971, remained until July 5, 1972, when the price was increased to £160 per metric ton (17.77 cents per pound U.S. equivalent). Although there was an increase in the European producer price, there was actually no increase in the equivalent cents per pound price because of the lowering average dollar value of the pound sterling. Another increase took place on November 27, at which time the price became £173 per metric ton (18.46 cents per pound U.S. equivalent).

FOREIGN TRADE

Exports of slab zinc dropped drastically from 13,346 tons to 4,324 tons in 1972, of which 88% was shipped to the United Kingdom. Exports of rolled zinc products, sheet, plate, strip, etc., increased 43% to 2,419 tons of which Canada received more than half, 1,329 tons.

General imports of zinc in ore declined 26% to 254,868 tons in 1972, reflecting smelter closures in 1971 and 1972 and decreasing availability of foreign concentrates. Canadian supplies of ore declined from 209,084 to 135,534 tons. Receipts from Mexico dropped from 89,845 to 57,315 tons, and receipts from Honduras dropped from 21,512 to 17,370 tons. Nicaragua supplied ores for the first time in 3 years in the amount of 10,960 tons of contained zinc. General imports of metal increased 64% to 522,612 tons in 1972. Canada was the largest supplier with 271,130 tons, an 80% increase over 1971. Other large suppliers of metal each ranging between 30,000 and 40,000 tons were Australia, Belgium-Luxembourg, West Germany, Japan, and Peru.

Imports of ore for consumption declined 63% from 467,368 tons in 1971 to 174,063 tons in 1972. The latter figure is significantly less than general imports which suggests a buildup of ores in the bonded warehouses. Metal imports for consumption increased 59% over 1971 to 516,643 tons in 1972, slightly less than the general imports of metal for the year. In addition, for the first time in the history of zinc, imports of metal were greater than the zinc metal produced from domestic ores, and the first time since 1937 imports of metal exceeded the quantity of zinc in imported ores and concentrates.

There were no changes in the tariff rates in 1972. The duties on unmanufactured zinc and zinc-containing materials were as follows: Slab zinc, 0.7 cent per pound; zinc ores, concentrates, and fume, 0.67 cent per pound (on zinc content less specified allowable deductions for processing losses); zinc scrap, 0.75 cent per pound; and zinc dust, 0.7 cent per pound. The duty rate for unwrought alloys of zinc, which includes diecasting alloys, was 19% ad valorem.

WORLD REVIEW

World mine production of zinc recovered from the temporary setback of 1971 to a rate more in keeping with the long-range forecast of demand proportional to world population growth. Zinc metal production also increased, setting a new record. World consumption resumed its upward climb with a 9% increase over the usage in 1971.

The world pattern was in sharp contrast to the situation in the United States where mine and smelter production decreased as consumption continued to grow, making the United States increasingly dependent on imported concentrates and metal. The possible source countries having an excess of at least 100,000 tons of mine production of zinc over internal consumption in 1972 were, in decreasing order of excess, Canada, Australia, Peru, Mexico, Poland, North Korea, Zaire, and Ireland. The first five of these were planning new smelter facilities or expansion of existing units in order to increase the proportion of metal refined in the source country. This worldwide trend will make concentrates less readily available to U.S. smelters and will increase U.S. dependency on metal imports.

New plants were planned or were under construction in Belgium, West Germany, the Netherlands, and Italy. New production will be partly offset by closures of old plants and so was expected to keep pace only with consumption growth within the EEC.

Algeria.—Société Nationale de Recherche et d'Exploitation Minière (Sonarem), the Algerian state mining agency, signed a contract with Dravo Corp. for the expansion and reconstruction of the El Abed lead-zinc mine to increase production from 800 to 3,300 tons per day.[32] Production of zinc (metal content) in 1972 was estimated to be about 18,300 tons.

The El Abed ores are part of the Bou-Beker deposits, which have been mined principally in Morocco but have been extended across the border into Algeria. The Touissit mine on the west end in Morocco was still operating, the Zellidja mine in the center and its small smelter in Morocco have been closed, and apparently the bulk of the ore reserves will now be at El Abed in Algeria. These reserves were estimated to contain 391,000 tons of zinc and 68,000 tons of lead, metal content.

Argentina.—The two zinc plants in Argentina achieved a new record output of about 45,000 tons of zinc metal. Mine production continued at a high level at Aguilar producing 50,204 tons of lead concentrate and 96,208 tons of zinc concentrate.[33] Mine production (metal content) was estimated at 40,000 tons. Consumption of zinc in Argentina remained about the same as in 1971 at 37,500 tons of metal.[34]

Australia.—Mine production of zinc in Australia rose 12% in 1972 to 554,000 tons, and refined zinc production rose 15% to 327,000 tons. Of this, 117,000 tons of slab zinc was consumed in Australia, two-thirds for galvanized products.[35] Only about 6,000 tons of zinc in Australian concentrate was exported to the United States, but 40,000 tons was exported to the U.S. as slab zinc; 133,000 tons of zinc in concentrate was exported to Japan.

The South Mine at Broken Hill (Broken Hill South Ltd.) was closed July 7, 1972. Operations at this mine began in 1885 and through acquisitions and leases had grown to include the whole central region of the Broken Hill lode, one of the great zinc mines of the world. The directors cited declining tonnage and grade of ore, adverse metal prices, and increased working costs as the reason for the closure.[36] Other parts of the Broken Hill lode were still being mined by the Zinc Corp. and New Broken Hill Consolidated, Ltd.

Production at some of the largest Australian zinc mines in 1972 was estimated as follows:

	Tons
Broken Hill South mine [1]	15,000
Zinc Corporation Ltd. mine, Broken Hill	87,000
New Broken Hill Consolidated mine	156,500
North Broken Hill [1]	48,000
Mount Isa Mines Ltd.	103,600
West Coast mines, Tasmania [1]	70,700

[1] Based on reports for fiscal year ending June 30, 1972.

Beneficiation tests have been completed by E.Z. Industries Ltd. for the willemite deposits at Beltana, South Australia, and treatment by fuming processes was investigated.

Several companies were exploring in the Captain's Flat area in New South Wales after Jododex Australia Proprietary Ltd. made a discovery reported to contain 7,000,000 tons of ore assaying 9.4% zinc, 2.0% copper, and 3.3% lead.[37]

The Australian Mining and Smelting Co. Ltd. (AM&S) through its subsidiary, Commonwealth Smelting Ltd., acquired the Imperial smelter at Avonmouth, in the United Kingdom on November 27, 1972. Another subsidiary of AM&S, Australian Overseas Smelting Pty. Ltd., engaged in a 50–50 joint venture to construct a new electrolytic zinc plant at Budel in the Netherlands. These ventures were intended to provide a secure outlet in the EEC for concentrates from New Broken Hill Consolidated Ltd. and Zinc Corp. mines, owned by AM&S.[38]

[35] Zinc Institute, Inc. A Review of Zinc in the United States in 1972. P. 14.

[36] Broken Hill South Ltd. 1972 Annual Report and Notice of Meeting. P. 5.

[37] World Mining. Base Metal Prospecting Excitement on Two Areas of New South Wales. V. 8, No. 12, November 1972, p. 52.

The electrolytic zinc refinery of E.Z. Industries Ltd. at Risdon, Tasmania, accounted for 62% of Australian zinc metal production, the smelter of Sulphide Corp. Pty. Ltd. at Cockle Creek, New South Wales, a subsidiary of AM&S, produced about 23%, and the zinc plant at the Port Pirie lead smelter of Broken Hill Associated Smelters Pty. Ltd., accounted for about 15%.

Belgium.—La Société des Mines et Fonderies de Zinc de la Vieille-Montagne, S.A. had four plants in Belgium and four in France concerned with zinc metal and zinc oxide production. In 1972 Vieille-Montagne produced a record 268,000 tons; capacity was expanded at the Balen, Belgium, electrolytic zinc plant and at the zinc oxide-zinc dust plant at Creil, France. The zinc-producing capacity of Vieille-Montagne in 1972 was 286,000 tons of electrolytic zinc and 55,000 tons of thermic zinc.[39] Other Belgian producers were Hoboken-Overpelt (121,000 tons capacity) and Société de Prayon, S.A. (68,000-ton capacity); Overpelt planned new construction to increase capacity by 1974, and Prayon completed a new electrolytic plant at Ehein, after closing its older retort plant.

Bolivia.—Although tin was the major metal produced and exported from Bolivia, zinc was second in value and first in tonnage in 1972. Zinc exports, mostly in concentrates, were 43,700 tons, metal content, with 30,100 tons coming from the Mina Matilde.

In December 1972, the Bolivian Government paid $13.4 million to Matilde Mine Corp. (United States Steel and Philipp Brothers., a division of Engelhard Industries Inc.) as indemnification for the nationalization of the Matilde plant in 1971. Production in 1972 was under Bolivian state mining corporation management Corporación Minera de Bolivia (COMIBOL). Ore was reported to run about 14% zinc and 1.1% lead. Concentrates were shipped across Lake Titicaca and to Japan through the Peruvian port of Matarani. COMIBOL also operated a few small zinc mines that sold concentrates for smelting in Peru. The "Medium Miners", made up of private companies smaller than COMIBOL, produced about 3,900 tons of zinc in concentrates.

Soviet and Polish interests conducted feasibility studies for the construction of zinc smelters to produce up to 50,000 tons of zinc annually at proposed sites near Corocoro and Potosí.

Brazil.—Zinc was produced at two plants, one operated by Companhia Mercantile Industrial Inga and the other by Companhia Mineira de Metais. Both produced electrolytic zinc from the silicate and oxide ores of Vazante, Minas Gerais. The Inga operation also produced small amounts of zinc oxide and zinc powder. The combined metal production of these two plants was 17,811 tons in 1972. Brazil depends on additional zinc imports to meet its requirements; its estimated consumption was 51,800 tons.

The two major zinc districts were at Vazante and Januaria in Minas Gerais. Januaria had no production in 1972. Both deposits produced calamine and willemite ores with residual amounts of sulfides. Reserves at Vazante were estimated at 2.5 million tons of contained zinc.[40]

Canada.—Mine production of zinc increased slightly in 1972 to 1.41 million short tons of zinc content in concentrates compared with 1.40 million tons in 1971. Zinc smelter production increased from 410,000 tons in 1971 to an estimated 525,400 tons in 1972. Hence, Canada retained its enormous lead as first in world zinc mine production and retained fourth rank in world zinc metal production. Several smelter expansions were planned to increase Canada's share of metal production in the future. Consumption of zinc in Canada in 1972 was estimated at 128,000 tons, an increase from the 1971 consumption of 111,000 tons. Obviously, Canada has the major part of its metal production available for export in addition to the large volume of zinc concentrates not converted to metal. Shipments of refined primary metal to the United States in 1972 were 276,200 tons and to other countries, 116,500 tons. Exports of concentrates from Canada decreased in 1972 to 752,000 tons (zinc content) from 866,200 tons in 1971, because more concentrates were converted to metal.

[38] New Broken Hill Consolidated Ltd. Holdings Ltd. 1972 Annual Report. P. 5.

[39] La Vieille-Montagne (Brussels, Belgium). Promotional Publications for Industry. September 1972, p. 31.

[40] Intermet Bulletin. V. 2, No. 2, October 1972, p. 15.

In the Northwest Territories, Cominco Ltd. continued to operate the Pine Point mines (69% Cominco owned) and mined 3.8 million tons of ore with an average grade of 2.7% lead and 6.2% zinc and probably recovered about 220,000 tons of zinc. Ore reserves reported at the end of the year were 40.9 million tons with average grade of 2.4% lead and 6.0% zinc.[41] Cominco started to develop a mine on Little Cornwallis Island in the Arctic Islands, 600 miles north of the Arctic circle, on the Polaris mine property of Arvik Mines Corp. Ltd. (75% Cominco, 25% Bankeno Mines Ltd.). A winter underground development program confirmed the existence of a deposit of 20 million tons of minable ore with a metal content of 20% combined zinc and lead.[42]

The Anvil Mining Corp. Ltd. completed the third year of operation at its open pit mine and concentrator near Faro, Yukon Territory. The mill treated nearly 8,000 tons of ore per day, the average grade was 10.8% combined lead and zinc. Concentrates sold contained 103,567 tons of lead and 114,682 tons of zinc. Anvil was owned 60% by Cyprus Mines Corp. and 40% by Dynasty Exploration, Ltd.[43] United Keno Hill Mines Ltd., at Elsa, Yukon Territory (48.4% Falconbridge) milled 81,000 tons of ore to produce 2,504,000 ounces of silver, 3,054 tons of lead, 1,653 tons of zinc, and 47,000 pounds of cadmium during 1972. Zinc production declined because of a decrease in ore grade. Two of the mines in the group were closed in the fourth quarter; exploration continued on other properties at Keno and near Whitehorse.[44]

British Columbia zinc production decreased about 12% in 1972, but zinc continued to be second only to copper in value of metals produced in the province. The estimated value of zinc production was about $47 million. Exploration activity decreased in 1971 and 1972 from the high rate of 1970; no major mineral properties were in the development stage in 1972. Five mines producing zinc-lead-silver ores operated with mill capacity as shown: Sullivan, 11,000 tons per day; Reeves MacDonald Annex, 1,000 tons per day; Nadina, 500 tons per day; Silmonac, 150 tons per day; and Highland Bell, 110 tons per day.[45] One copper-lead-zinc-silver mine, the Lynx, was operated at Buttle Lake at a rate of 750 tons per day. Cominco was the major producer at its Sullivan mine, mining 1,925,000 tons with a combined zinc-lead grade of 10.8%. Traditionally this mine has produced about 100,000 tons of zinc per year. Bralorne Resources was managing a joint venture, "Bradina", with Pacific Petroleum Ltd. to bring into production the Nadina mine at Owen Lake south of Houston. The mill began production in May 1972. Ore reserves were estimated to be 551,650 tons with average grade of 0.1 ounce of gold and 10 ounces of silver per ton, 0.76% copper, 2.1% lead, and 6.96% zinc. The bulk lead-zinc concentrate is contracted to Japanese companies.[46] The Reeves MacDonald Mines Ltd. continued to produce concentrates destined for the Bunker Hill smelter from the Annex mine at the rate of about 10,000 tons of zinc per year.[47] Kam-Kotia and Burkam Mines Ltd. continued a joint venture operating the Silmonac property in the Slocan district and shipping ore to the nearby Carnegie mill. In 1971, ore had an average grade of 6.39% lead, 6.6% zinc, and 17.99 ounces of silver per ton and produced 2,400 tons of contained zinc shipped to the Bunker Hill smelter. The Highland Bell or Beaverdell property with values chiefly in silver was operated by Teck Corp. Ltd. with zinc concentrates going to Cominco at Trail at the rate of about 300 tons of zinc metal per year.[48] Western Mines Ltd. operated the Lynx mine and developed the nearby Myra group at Buttle Lake on Vancouver Island. Ownership by W. R. Grace & Co. was increased to 25% during 1972.[49] The Lynx mine produced 22,900 tons of zinc in 1971.

[47] Pend Oreille Mines and Metals Co. Nine Months Report. Sept. 30, 1972, p. 2.

[48] G. S. Barry. Zinc. Can. Min. J., v. 94, No. 2, February 1973, p. 89.

Cominco announced plans late in 1972 to reopen the H. B. zinc-lead mine near Salmo, British Columbia, replacing the production that formerly came from the Bluebell mine, which closed late in 1971. Production was planned to be 1,000 tons per day early in 1973.

The Hudson Bay Mining & Smelting Co. Ltd. brought into production two new mines in Manitoba in 1972, the White Lake mine with a daily production of 450 tons and the Ghost Lake mine with a daily output of 250 tons. The Flexar mine in Saskatchewan, with a rate of 340 tons per day, was closed in November 1972. The company now operates nine base metal mines in the Flin Flon region. Reserves given for White Lake are 330,000 tons, 5.4% zinc, 2.6% copper; reserves for Ghost Lake are 290,000 tons, 14.5% zinc, 1.58% copper. Taking the nine or more mines as a whole, Hudson Bay reports ore reserves of 17,288,600 tons, 2.9% copper, 3.3% zinc, 0.04 ounce gold, and 0.6 ounce silver. The zinc refinery treated 87,832 tons of 48.0% zinc concentrate from Hudson Bay mines, 42,901 tons of purchased 52.5% zinc concentrate and 41,651 tons of 60.4% zinc oxide fume to produce 77,023 tons of zinc.[50]

Sherritt Gordon Mines, Ltd., was a substantial zinc producer in Manitoba with a copper-zinc operation at the Fox mine and a copper-zinc project under development at the Ruttan mine. The Fox mine produced 4,493 tons of zinc in 1972. Construction work at the Ruttan pit progressed through 1972, and production was expected to start in 1973. Ore reserves at the Fox mine were 13,300,000 tons, 2.01% copper, 2.23% zinc and at the Ruttan mine were 51,000,000 tons, 1.47% copper and 1.61% zinc. (Lynn Lake reserves were in nickel and copper values and were not published in 1972.) [51]

The Kidd Creek mine of Texasgulf, Inc., near Timmins, Ontario, continued to be Canada's largest zinc producer. The open pit mine is the present source of most of the copper, lead, zinc, silver, and cadmium production, but the underground mine (a downward extension of the ore in the pit) was being developed so that it can supply 2,000 tons per day by the end of 1973 and will eventually supply the entire 10,000 tons daily required for concentrator feed after the next several years. Zinc production in 1972 was 616,700 tons of 52% concentrate for about 320,000 tons of zinc. Part of this concentrator production was used to produce 60,100 tons of zinc metal in the new zinc plant. The zinc plant conversion from batch leaching to a continuous operation was started in 1972 and should be completed by 1974; this change will increase annual zinc metal capacity from 120,000 to 150,000 tons.[52]

Mattabi Mines, Ltd., owned 60% by Mattagami Lake Mines Ltd., and 40% by Abitibi Paper Co. Ltd., began production in July 1972 at a new open pit operation near Ignace, Ontario. The design rate of 3,000 tons per day was almost realized during the 5 months of full operation. Ore treated averaged 11.97% zinc, 1.27% copper, 1.27% lead, and 4.99 ounces of silver per ton. Ore reserves reported July 1972 were 12,866,000 tons, 7.60% zinc, 0.91% copper, 0.84% lead, and 3.13 ounces of silver per ton. Zinc concentrates produced were shipped to Canadian Electrolytic Zinc Ltd. at Valleyfield, Quebec, to Quebec City for export and to the United States; the zinc portion of mill production was 80,378 tons of concentrates grading 55.14%.[53]

The Geco mine, operated by Noranda Mines Ltd. in the Manitouwadge area, Ontario, mined 1,815,000 tons of ore that averaged 2.12% copper, 4.30% zinc, and 1.93 ounces of silver per ton; concentrates contained 61,300 tons of zinc. Ore reserves at yearend were 29,400,000 tons with average grade 1.94% copper, 4.22% zinc, and 1.75 ounces of silver per ton.[54]

Jameland Mines Ltd., owned 30.3% by Kam-Kotia Mines Ltd., sent ore to the Kam-Kotia mill in 1972, but closed its copper-zinc mine December 30, 1972.[55] Concentrates produced in 1971 contained 1,661 tons of zinc destined for U.S. smelters.

Willroy Mines Ltd. continued to operate the Willroy mill at the rate of 1,600 tons per day on ores from the Willroy and Willecho properties in the Manitouwadge area. Ore processed was 431,067 tons averaging 1.10% copper, 3.27% zinc, and 1.41 ounces of silver per ton (estimated 11,500 tons zinc). Ore reserves at the end of the year were 936,000 tons, 0.78% copper, 3.95% zinc, and 1.71 ounces of silver per ton.[56]

[53] Mattagami Lake Mines Ltd. 1972 Annual Report. P. 6.

[54] Noranda Mines Ltd. 1972 Annual Report. P. 10.

[55] Page 85 of work cited in footnote 48.

Selco Mining Corp. Ltd. operated the South Bay mine in the Uchi Lake area to feed its 500-ton-per-day mill, which produces zinc concentrates for export to France and copper-silver concentrates for Noranda. For the year ending March 31, 1972, the mill treated 175,100 tons of ore grading 2.29% copper, 13.11% zinc, and 3 ounces of silver per ton (to produce an estimated 18,000 tons of zinc). Ore reserves were 580,000 tons, 2.27% copper, 14.24% zinc, and 3.69 ounces of silver per ton after allowance for recovery and dilution.[57]

The largest zinc mine production in the province of Quebec came from the Mattagami mine of Mattagami Lake Mines, Ltd. Ore milled in 1972 totaled 1,370,167 tons, 7.4% zinc, 0.56% copper, 0.017 ounce of gold per ton, and 0.88 ounce of silver per ton. Zinc concentrates produced contained 89,850 tons of zinc. Ore reserves without allowance for dilution, were 14,661,927 tons, 8.9% zinc, 0.67% copper, 0.012 ounce of gold and 1.08 ounces of silver per ton. Mattagami Lake Mines owns 51.7% of the Canadian Electrolytic Zinc plant at Valleyfield and Noranda owns 31.4% of Mattagami Lake. Exploration conducted by Mattagami Lake has developed about 2,000,000 tons of ore reserves in the Sturgeon Lake area of Ontario, grading 6% to 8% zinc with copper, lead, gold, silver values; more drilling remains to be done in this area.[58]

Orchan Mines Ltd., owned 47.1% by Noranda Mines Ltd., is another major zinc producer in Quebec. The Orchan mill treated 376,800 tons of ore, 10.6% zinc and 1% copper including 2,700 tons from the new Garon Lake development at the end of the year. Reserves in the Orchan mines were 1,897,000 tons, 9% zinc and 1.2% copper. Additional reserves were being developed on the Garon Lake and Norita properties, both within truck-hauling distance of the Orchan mill.[59] Based on 1971 mill performance, Orchan probably produced 36,000 tons of zinc in 1972.

Kerr Addison Mines, Ltd., 43.6% owned by Noranda, operated the Normetal mine in northwestern Quebec. The concentrator milled 326,500 tons of ore assaying 1.73% copper, 5.29% zinc, 0.026 ounce of gold per ton, and 1.43 ounces of silver per ton. Zinc concentrates contained 14,666 tons of zinc. Ore reserves on December 31, 1972, were 271,000 tons, 1.6% zinc; production is expected to cease during the third quarter of 1973.[60] Kerr Addison also controlled Joutel Copper Mines, Ltd., which during 1972 converted the Joutel mill to treat zinc rather than copper ores. The zinc-bearing part of 1972 production was 70,200 tons averaging 12.16% zinc, producing 6,334 tons of zinc in concentrates. Reserves at yearend were 72,600 tons averaging 2.02% copper and 144,600 tons averaging 11.18% zinc, all of which was scheduled for mining in 1973.

Falconbridge Copper Ltd. operated the Lake Dufault division in western Quebec. The mill treated 562,000 tons of ore containing 3.16% copper and 4.39% zinc, mostly from the Millenbach mines, and produced 19,109 tons of zinc in concentrates. The Norbec mine will be mined out during 1973, and thereafter production will come from the Millenbach mine and the Norbec stockpile. Ore reserves at yearend were 2,835,000 tons with an average grade of 3.1% copper and 3.9% zinc.[61] Falconbridge's subsidiary, Sturgeon Lake Mines Ltd., completed an engineering estimate for the development of a 1,200-ton-per-day operation near the Mattagami Lake property. Ore reserves of 1,928,000 tons, 3% copper, 7.85% zinc, and 4.54 ounces of silver per ton were considered to be available for a future open pit operation.

Manitou-Barvue Mines Ltd., near Val-d'Or, has been treating copper ore from Louvem Mining Co. but has also announced plans to reopen its silver-zinc mine in Bourlamaque.

In the Eastern Townships of Quebec, the Sullivan Mining Group Ltd. operated the Cupra, D'Estrie and Weedon mines.

[59] Page 14 of work cited in footnote 54.

[60] Page 4 of work cited in footnote 12.

[61] Page 30 of work cited in footnote 44.

The group produced 9,115 tons of zinc in fiscal 1972, along with copper, cadmium, and bismuth. Sullivan's Nigadoo River Mines Ltd. subsidiary closed its mine and mill in New Brunswick in January 1972.

The Brunswick Mining & Smelting Corp. Ltd., 64% owned by Noranda, accounted for the major part of New Brunswick zinc mine production. The No. 12 mine and No. 6 mine together produced 3,257,600 tons of ore containing 9.92% combined lead and zinc.[62] Part of the zinc concentrates were treated in the Belledune smelter, but in January the conversion of the Imperial smelting process to lead smelting only was begun, and a large part of the zinc concentrates was sold abroad. An estimate of the recoverable zinc metal produced by the mines was 184,000 tons. Zinc-bearing ore reserves for the two mines were about 78,000,000 tons averaging approximately 9% zinc, 3.7% lead, 2.7 ounces of silver per ton, and 0.3% copper.

Heath Steele Mines Ltd., owned by AMAX, was the only other zinc producer in New Brunswick. During 1972, 836,000 tons of ore was mined yielding 48,000 tons of zinc concentrate, 22,000 tons of lead concentrate, and 23,000 tons of copper concentrate.[63] Concentrates were shipped to the United States and Europe; estimated zinc content was 23,000 tons.

Newfoundland had one substantial zinc producer, the Buchans mine of ASARCO. Production of lead, zinc, and silver was almost double that of 1971; 30,000 tons of zinc, 17,800 tons of lead and 959,000 ounces of silver.[64] Ore reserves were determined sufficient for 6 years production based on present costs and prices.

Zinc smelter production increased in Canada during 1972 as a combined result of near-capacity utilization of existing facilities and the new facility of Ecstall Mining Ltd. (Texasgulf) coming onstream as scheduled in 1972. Brunswick Mining & Smelting Corp. ceased production of zinc metal during 1972 as the Imperial type smelter at Belledune, New Brunswick, was converted to a lead smelter in January. Canadian Electrolytic Zinc announced plans to expand its Valleyfield plant from the current capacity of 140,000 tons per year to 225,000 tons per year by 1975.[65] Cominco started construction on a battery of electrolytic zinc cells that will add 10,000 tons per year of refined zinc at the Trail operations.[66] Cominco's production was held back in July 1972 by a 1-month strike.

A summary of Canadian slab zinc production is given in the following tabulation:

Company	Current capacity	Production in 1972, short tons	Planned capacity in 1973–75, short tons per year
Canadian Electrolytic Zinc Ltd., Valleyfield, Quebec	140,000	145,000	225,000
Cominco Ltd., Trail, British Columbia	295,000	243,000	305,000
Hudson Bay Mining & Smelting Co. Ltd., Flin Flon, Manitoba	79,000	77,023	79,000
Ecstall Mining Ltd., Timmins, Ontario	120,000	60,100	150,000
Total	634,000	525,123	759,000

Germany, West.—West German mines produced ore containing 134,658 tons of zinc, and West German smelters and refineries turned out 395,000 tons of zinc, including secondary and remelted products, a 37% increase from the total metal production of 1971. The new Preussag electrolytic zinc refinery at Nordenham contributed about 92,000 tons to the total.

Italy.—A new lead-zinc Imperial-type smelter began operation at Porto Vesme on the island of Sardinia late in the year. Output by Azienda Minerali Metallici Italiane (AMMI) Sarda, S.p.A., was expected to be about 75,000 tons per year of "Grade 4" zinc, most of which will be used to produce 66,000 tons per year of Special High grade zinc. The operation used ores from the Dell' Isola area on southwest Sardinia. Local reserves included oxide ores that were treated by a heavy-media concentrating process followed by a Waelz kiln to produce oxide that was blended with sulfide flotation concentrate to make a feed for the Imperial furnace.

Japan.—Japan had a similar experience to the United States in 1972; some of its zinc mines were closed and smelter operations curtailed by the public outcry against pollution. Japanese industrialists looked increasingly abroad for future sources of zinc concentrates. Nevertheless, the zinc smelting industry of Japan achieved a record production of 887,700 tons of zinc metal, leading the world in slab zinc production.

Akita Zinc Co. Ltd. planned to increase capacity of its Iijima smelter and refinery by 86,000 tons per year by June 1974, and Mitsui Mining & Smelting Co. Ltd. was considering an expansion of the order of 60,000 tons per year at its Hikoshima refinery, possibly by late 1974.[67]

Mexico.—Mine production of zinc during 1972 increased about 3% to 299,656 tons. The three metal producers, Asarco Mexicana S.A. at Rosita, Zincamex S.A. at Saltillo, and Zinc Industrial at Tlalnepantla produced about 93,000 tons of refined zinc.

Industrias Peñoles, S.A., developed sources of zinc concentrates, as well as lead, copper, and silver at its Mina Reforma and Mina La Negra. Its electrolytic zinc refinery at Torreón, with a planned annual capacity of 115,700 tons of refined zinc, was under construction and was expected to begin operation in September 1973.

Asarco Mexicana, S.A., produced 118,900 tons of zinc as metal and as content of concentrates sold during 1972, a 4% decrease from 1971 production.[68]

A proposed project for a 100,000-ton-per-year zinc refinery, possibly to be located in the State of San Luis Potosí, was under study at yearend.[69] An earlier report linked a group of Japanese mining companies and the Mexican Government in the formation of a nonferrous metal development company to start prospecting in Sonora.[70]

Netherlands.—Proposed construction of an electrolytic zinc smelter at Budel, which would have 165,000-ton-per-year capacity, was announced early in 1972. Australian Mining and Smelting Co. and Billiton will each own half; Billiton will manage the smelter.[71] The existing retort smelter at Budel produced 55,000 tons of zinc in 1972.

Peru.—Production of refined zinc by Cerro Corp. increased to 74,425 tons, a gain of 18% over production in 1971. Production of zinc in concentrates for export also increased about 31% to 115,365 tons. Cerro operations in Peru returned to a more normal level of efficiency with relatively few work interruptions in 1972 in contrast to the many strikes in 1971.[72]

Compañia Minerales Santander Inc., a subsidiary of St. Joe Minerals Corp., operated a zinc-lead mine that produced about 74,000 tons of zinc concentrates marketed by a Peruvian Government agency.[73]

The total zinc production of Peru included the 74,000 tons of Cerro refined metal production, 600 tons as sulfates, 317,000 tons of ores and concentrates for export, and 2,300 tons of zinc powder. Much of the zinc concentrate production was exported to Japan.

Poland.—Zinc production in Poland was forecast to grow from 251,000 tons in 1972 to 258,000 tons in 1975. The expansion may be accomplished by increasing the capacity of the Imperial-type smelter at Miasteczko Slaskie as the old retorting methods are replaced.[74]

South Africa, Republic of.—The Prieska copper-zinc mine in northeast Cape Province of the Republic of South Africa began trial milling in October; half of the production of zinc concentrates, estimated to be 100,000 tons annually, will go to the Zinc Corp. of South Africa Ltd. (ZINCOR) and half to the export market.[75] ZINCOR also drew concentrates from the Rosh Pinah and Berg Aukas mines in the Territory of South-West Africa. Zinc metal production by ZINCOR in 1972 exceeded 50,000 tons, and an expansion was announced to raise capacity to 69,000 tons by 1973.

Spain.—Two companies produced zinc in Spain, Asturiana del Zinc at San Juan de Nieves and Española del Cinc, S. A. at La Asomada near Cartagena, for a total metal output of about 110,000 tons. Spanish mines produced about 90% of its smelting requirements, and the discovery of new deposits in southeast Spain should allow the country to be self-sufficient within a few years.

Sweden.—The Belgian firm, Vieille Montagne, announced plans to double production of zinc concentrates at its Zinkgruvan mine at Ammeberg in central Sweden. The ore was reported to contain 9% zinc and 1.5% lead and, by 1976, production should reach 660,000 tons per year of ore yielding concentrates containing 53,000 tons of zinc. Other mines in Sweden were operated by The Boliden Co. and other producers to make a total estimated production for 1972 of 121,000 tons of zinc in concentrates.

Turkey.—An agreement was signed for financing in Canada the equipment for the development of a new zinc mine and electrolytic smelter in the Zamanti Valley. Projected plant capacity was 44,000 tons of zinc annually with production ready in 1975.[76] Production of ores and concentrates from Turkish mines was 27,155 tons in 1972 including crude ore, calcined concentrates and hand-sorted ore.

Yugoslavia.—Zinc metal production in Yugoslavia was below expectation in the early part of 1972, and the final estimated slab zinc production of 53,600 tons was lower than the 58,500 tons produced in 1971. The new smelter under construction at Titov Veles was planned to produce 65,000 tons of zinc per year and will double the capacity of Yugoslavia to 130,000 tons per year. Other plants at Sabac-Zorka, Zvečan-Trepča, and Celje produced in the range of 20,000 to 40,000 tons annually. Yugoslavian mines produced about 106,600 tons of zinc in concentrates in 1972.

TECHNOLOGY

Zinc Abstracts, a monthly publication, prepared jointly by the Zinc Development Association, 34 Berkeley Square, London, and the Zinc Institute, Inc., 292 Madison Avenue, New York, N.Y. 10017, provides an extensive review of current world literature on the uses of zinc and its products. The abstracts are provided free of charge to bona fide inquirers from the Zinc Institute, Inc.

The International Lead Zinc Research Organization, Inc. (ILZRO), reviews progress twice a year on lead and zinc research and development programs conducted under the direction of ILZRO. The Research Digests, which review the projects, are also available from the Zinc Institute, Inc.

Research was conducted by the Bureau of Mines during the year concerning processing lead-zinc concentrates, recovery and uses of secondary copper and zinc, and changes in the zinc supply-demand pattern. Several reports of investigations and professional papers were published by the Bureau of Mines and the Geological Survey.[77]

Table 13.—Production of zinc products from zinc-base scrap in the United States

(Short tons)

Product	1968	1969	1970	1971	1972
Redistilled slab zinc	79,865	70,553	77,156	80,923	90,297
Zinc dust	37,903	33,747	29,605	29,095	40,569
Remelt spelter	3,580	3,978	3,494	1,590	5,850
Remelt die-cast slab	14,570	16,979	16,686	18,339	13,555
Zinc-die and diecasting alloys	4,128	4,401	4,361	3,316	3,927
Galvanizing stocks	2,107	1,849	762	633	872
Secondary zinc in chemical products	45,654	45,298	[r] 42,238	[r] 45,312	50,047

[r] Revised.

Table 14.—Zinc recovered from scrap processed in the United States, by kind of scrap and form of recovery

(Short tons)

Kind of scrap	1971	1972	Form of recovery	1971	1972
New scrap:			As metal:		
Zinc-base	140,854	145,620	By distillation:		
Copper-base	135,201	158,834	Slab zinc [1]	79,754	88,988
Aluminum-base	2,833	3,649	Zinc dust	28,542	40,123
Magnesium-base	222	281	By remelting	2,127	6,674
Total	279,110	308,384	Total	110,423	135,785
Old scrap:			In zinc-base alloys	24,307	16,480
Zinc-base	44,876	42,998	In brass and bronze	[r] 171,947	177,377
Copper-base	31,308	32,456	In aluminum-base alloys	6,535	7,638
Aluminum-base	3,587	3,854	In magnesium-base alloys	627	434
Magnesium-base	272	69	In chemical products:		
			Zinc oxide (lead-free)	[r] 22,181	25,897
Total	80,043	79,377	Zinc sulfate	10,335	11,076
			Zinc chloride	10,111	11,126
Grand total	359,153	387,761	Miscellaneous	2,687	1,948
			Total	248,730	251,976
			Grand total	359,153	387,761

[r] Revised.

[1] Includes zinc content of redistilled slab made from remelt die-cast slab.

Table 15.—Zinc dust produced in the United States

Year	Quantity (short tons)	Value	
		Total (thousands)	Average per pound
1968	61,566	$22,041	$0.179
1969	55,055	21,361	.194
1970	51,136	20,045	.196
1971	50,259	19,691	.196
1972	59,358	24,669	.208

Table 16.—Consumption of zinc in the United States

(Short tons)

	1968	1969	1970	1971	1972
Slab zinc	1,350,656	1,385,380	1,186,951	1,254,059	1,418,349
Ores (recoverable zinc content) [1]	124,109	126,712	124,781	119,254	118,305
Secondary (recoverable zinc content) [2]	270,592	302,075	259,864	[r] 277,381	292,099
Total	1,745,357	1,814,167	1,571,596	[r] 1,650,694	1,828,753

[r] Revised.

[1] Includes ore used directly in galvanizing.

[2] Excludes redistilled slab and remelt zinc.

Table 17.—Slab zinc consumption in the United States, by industry use

(Short tons)

Industry and product	1968	1969	1970	1971	1972
Galvanizing:					
Sheet and strip	273,276	268,682	253,155	255,335	294,205
Wire and wire rope	36,089	32,348	30,857	29,895	30,769
Tubes and pipe	63,621	65,898	64,479	65,122	64,549
Fittings (for tube and pipe)	13,801	11,418	9,498	10,240	11,106
Tanks and containers	3,815	5,561	3,924	2,759	3,645
Structural shapes	20,238	19,454	18,761	18,589	20,302
Fasteners	4,826	5,536	5,318	5,159	4,310
Pole-line hardware	9,050	9,409	9,938	8,358	8,437
Fencing, wire, cloth, and netting	15,984	17,984	18,114	20,232	21,995
Other and unspecified uses	58,074	57,091	60,205	59,063	58,886
Total	498,774	493,381	474,249	474,752	518,204
Brass products:					
Sheet, strip, and plate	86,185	90,777	61,672	78,929	105,405
Rod and wire	49,888	56,989	41,459	46,514	63,143
Tube	9,818	10,928	9,086	9,399	8,886
Castings and billets	2,286	5,958	4,606	4,479	6,840
Copper-base ingots	12,153	13,642	9,946	10,440	7,137
Other copper-base products	1,576	1,175	978	725	736
Total	161,906	179,469	127,747	150,486	192,147
Zinc-base alloys:					
Diecasting alloy	551,896	565,839	453,490	504,823	566,932
Dies and rod alloy	807	504	87	270	56
Slush and sandcasting alloy	10,243	10,048	10,059	11,018	12,773
Total	562,946	576,391	463,636	516,111	579,761
Rolled zinc	48,943	48,650	41,065	38,852	45,216
Zinc oxide	34,937	41,447	43,829	40,043	51,992
Other uses:					
Light-metal alloys	8,422	7,562	3,985	4,575	6,300
Other [1]	34,728	38,480	32,440	29,240	24,729
Total	43,150	46,042	36,425	33,815	31,029
Grand total	1,350,656	1,385,380	1,186,951	1,254,059	1,418,349

[1] Includes zinc used in making zinc dust, wet batteries, desilverizing lead, bronze powder, alloys, chemicals, castings, and miscellaneous uses not elsewhere mentioned.

Table 18.—Slab zinc consumption in the United States in 1972, by grade and industry use

(Short tons)

Industry	Special high grade	High grade	Intermediate	Brass special	Prime [1] western	Remelt	Total
Galvanizing	30,585	24,972	70	120,855	341,106	616	518,204
Brass and bronze	38,474	106,317	133	9,034	38,099	90	192,147
Zinc-base alloys	569,460	9,074	11	181	639	396	579,761
Rolled zinc	20,384	--	18,967	--	5,865	--	45,216

Total	697,581	144,228	19,990	130,079	425,359	1,112	1,418,349

[1] Includes select grade.

Table 19.—Rolled zinc produced and quantity available for consumption in the United States

	1971			1972		
	Short tons	Value		Short tons	Value	
		Total (thousands)	Average per pound		Total (thousands)	Average per pound
Production:[1]						
Photoengraving plate	11,290	$8,259	$0.390	13,418	$10,118	$0.377
Sheet zinc less than 0.375 inch thick	W	W	W	--	--	--
Strip and foil	25,342	13,656	.269	28,189	17,100	.303
Total rolled zinc[2]	38,263	23,399	.306	45,216	28,820	.319
Exports	1,686	1,486	.441	2,419	2,138	.442
Imports	509	237	.233	485	310	.320
Available for consumption	38,390	--	--	43,057	--	--

W Withheld to avoid disclosing individual company confidential data; included in total.

[1] Figures represent net production. In addition, 20,276 tons in 1971 and 41,764 tons in 1972 were rerolled from scrap originating in fabricating plants operating in connection with zinc-rolling mills.

[2] Includes other plate over 0.375 inch thick rod and wire, and strip and foil. Bureau of Mines not at liberty to publish separately.

Table 20.—Slab zinc consumption in the United States in 1972, by industry and State

(Short tons)

Total[4]	517,588	192,057	579,365	128,227	1,417,237

W Withheld to avoid disclosing individual company confidential data; included with "Undistributed."

[1] Includes brass mills, brass ingot makers, and brass foundries.

[2] Includes producers of zinc-base alloy for diecastings, stamping dies, and rods.

[3] Includes slab zinc used in rolled zinc products and in zinc oxide.

[4] Excludes remelt zinc.

Table 21.—Production and shipments of zinc pigments and compounds[1] in the United States

Pigment or compound	1971				1972			
	Production (short tons)	Shipments			Production (short tons)	Shipments		
		Quantity (short tons)	Value[2]			Quantity (short tons)	Value[2]	
			Total (thousands)	Average per ton			Total (thousands)	Average per ton
Zinc oxide[3]	214,952	227,503	$72,910	$320	237,015	245,867	$84,244	$343
Zinc sulfate	45,929	49,303	6,333	128	38,897	39,595	5,220	132

[1] Excludes leaded zinc oxide, lithopone, and zinc chloride; figures withheld to avoid disclosing individual company confidential data.

[2] Value at plant, exclusive of container.

[3] Zinc oxide containing 5% or more lead is classed as leaded zinc oxide.

Table 22.—Zinc content of zinc pigments[1] and compounds produced by domestic manufacturers, by source

(Short tons)

Pigment or compound	1971					1972				
	Zinc in pigments and compounds produced from—				Total zinc in pigments and compounds	Zinc in pigments and compounds produced from—				Total zinc in pigments and compounds

[e] Estimate. [p] Preliminary. [r] Revised.

[1] In addition to the countries listed, North Vietnam also produces zinc, but available information is inadequate to make reliable estimates of output levels.

[2] Zinc content of concentrates.

[3] Sum of production by COMIBOL and exports by medium and small mines.

[4] Data are total of output for Rosh Pinah mine, Berg Aukas mine, and Tsumeb Corp. for years ended June 30 of that stated except for 1972; in 1972 Tsumeb Corp. data is for calendar 1972 and that for the other two properties is for year ended June 30, 1972. In the period July 1, 1971 to December 31, 1971, Tsumeb Corp. produced 3,162 short tons of zinc in concentrates, which is not included in above figures.

[5] Year beginning March 21, of year stated.

[1] In addition to the countries listed, North Vietnam also produces zinc, but available information is inadequate to make reliable estimates of output levels.

[2] Includes production from reclaimed scrap.

Zirconium and Hafnium

By Sarkis G. Ampian [1]

Zircon production and sales by domestic mining companies were about 20% greater in 1972 than in 1971. Zircon exports increased 84% from 9,429 tons in 1971 to 17,360 tons in 1972 while imports decreased 30% from 96,387 short tons in 1971 to 67,537 short tons in 1972. Exports of zirconium oxide, zirconium metal, and zirconium alloys all rose in 1972. Production of zirconium-bearing compounds for chemicals and refractories also increased. Zircon consumption by foundries declined nearly 20%, from 116,000 short tons in 1971 to 92,000 tons in 1972. However, foundry consumption of zircon was increasing at yearend.

Legislation and Government Programs.—The Statistical Supplement to the Stockpile Report to Congress, December 31, 1972, showed no objectives for zirconium and hafnium materials. Stocks of 15,998 tons of Brazilian baddeleyite and 1 ton of zirconium metal powder are in excess. The U.S. Atomic Energy Commission (AEC) had an inventory as of June 30, 1972, of approximately 1 ton of zirconium crystal bar and scrap, 1,063 tons of zirconium sponge, 84 tons of Zircaloy ingot and shapes, 2 tons of hafnium scrap, 47 tons of hafnium oxide, 1/2 ton of hafnium sponge and shapes, and 39 tons of hafnium crystal bar.

[e] Estimate. W Withheld to avoid disclosing individual company confidential data.

[1] Includes baddeleyite: 1968—200 tons; 1969—383 tons; 1970—355 tons; 1971—871 tons; 1972—385 tons.

[2] Excludes foundries.

[3] Excludes oxide produced by zirconium metal producers.

DOMESTIC PRODUCTION

E. I. du Pont de Nemours & Co., and Titanium Enterprises, Inc., a new producer, were the only major producers of zircon mineral concentrate in the United States. Zircon was recovered from mineral sands at the dredging and milling facilities owned by du Pont at Starke, Fla., by Humphreys Mining Co. for du Pont, near Folkston, Ga., and Titanium Enterprises at Green Cove Springs, Fla. Production data were withheld from publication to avoid disclosing individual company confidential data. The combined zircon capacity of these three plants is estimated to be 125,000 tons per year.

Statistical data on production of zirconium sponge, ingot, and scrap and on hafnium sponge and oxide are also withheld to avoid disclosure of company confidential data. Zirconium powder, zirconium-base alloys, and zirconium sponge metal production were relatively unchanged from those reported for 1971. Approximately 5,000 tons of alloys containing from 3% to 70% zirconium was produced in 1972.

---

[1] Physical scientist, Division of Nonmetallic Minerals.

Three firms produced 45,000 tons of milled (ground) zircon, a decrease of nearly 5% from the reported 1971 production. Six companies, excluding those that produce metal, produced 12,020 tons of zirconium oxide. Oxide production in 1972 increased nearly 12% over that reported in 1971. Production of zirconium-bearing refractories totaled 43,000 tons, containing from 33% to 95% zirconium oxide.

Hafnium crystal bar, produced by several firms, amounted to 40 tons, compared with 32 tons in 1971.

CONSUMPTION AND USES

Zircon consumption in the United States in 1972 was estimated at 168,000 tons. Consumption of zircon concentrate and milled zircon was 92,000 tons for foundries, 25,000 tons for refractories, 18,000 tons for zirconium oxide, 3,000 tons for zirconium alloys (excluding zirconium-base alloys), and 30,000 tons for all other uses. Foundries

Wah Chang Albany Corp	Albany, Oreg	Oxide, sponge metal, crystal bar, ingot.

consumed 51% of the domestic zircon production. The remaining 49% was consumed by refractory, ceramic, metal, and other industries. Domestic zircon was also marketed in proprietary mixtures for use as weighting agents, zircon-TiO_2 blends for welding rod manufacture, and zircon-refractory heavy mineral (kyanite, sillimanite, and staurolite) sand blends, for foundry sand and sandblasting applications. The zircon-bearing foundry sand was reportedly designed to provide consistent high-quality performance at low cost for critical casting applications.

Imported Republic of South Africa baddeleyite ore in 1972 was used mostly in the manufacture of alumina-zirconia abrasives, and used also in ceramic colors, refractories, and other uses.

Preliminary Bureau of the Census figures for 1972 showed that shipments of zircon and zirconia brick and shapes, composed mostly of these materials, totaled 1.7 million brick, expressed in terms of equivalent 9-inch brick, valued at $6.2 million. In 1971, final figures for shipments were 1.9 million brick valued at $6.9 million.[2]

Dealers and other firms reported shipments of milled zircon and concentrate in 1972 to the following markets: Foundry use, 42,000 tons; refractory and chemical uses, 52,000 tons; chemical, metal, alloying, compounds, and other uses, 4,200 tons.

Zirconium metal was used in nuclear reactors, in chemical plants for corrosion-resistant material, in refractory alloys, and in photography for flashbulbs. AMAX Specialty Metals, Inc. acquired a new metal-rolling facility. The new facility will be used to produce flat products, such as plate, sheet, strip, and foil, from zirconium and molybdenum alloys and metals.

Zirconium compounds, natural and manufactured, were also used in refractories, glazes, enamels, welding rods, chemicals, and sandblasting, Zirconium chemicals were finding increasing applications in the paint, textile, and pharmaceutical industries. Ionarc/TAFA recently began streamlining its pilot commercial-scale ZrO_2 plant. This new plant was scheduled for

Table 3.—Zircon consumption in selected zirconium materials as reported by producers in the United States in 1972

completion by the summer of 1973 with a projected capacity of 1 million pounds per year of their unique plasma-produced zirconia. This highly reactive zirconia, readily soluble in sulfuric acid, was reported to be particularly suited for zirconia-based colors, chemicals, and polishes.

Hafnium metal, alloys, and compounds continued to have few uses. The metal was used for nuclear reactor control rods, in special refractory alloys, and in photographic flashcubes. The nonnuclear hafnium metal uses were reportedly increasing.

PRICES

Published prices of zircon, zirconium oxides and chemicals, zirconium hydride, zirconium metal powder and sponge, and hafnium metal products were relatively unchanged from those of 1971. The baddeleyite price was furnished by Ronson Metals Corp.

Table 6.—Published prices of zirconium and hafnium materials in 1972

Specification of material	Price
Zircon:	
Domestic, f.o.b. Starke, Fla. (Folkston, Ga.) bags, per short ton [1]	$54.00 –$55.00
Domestic, 75% minimum quantity zircon and aluminum silicates, Starke, Fla. (Folkston, Ga.) bags, per short ton	40.00
Imported sand, containing 65% ZrO_2, c.i.f. Atlantic ports, bags, per long ton [2]	65.00 – 70.00
Domestic, granular, 30-ton lots, from works, bags, per pound [3]	.04875
Domestic, milled, 15-ton lots, from works, bags, per pound [3]	.050
Baddeleyite imported concentrate:[4]	
98%–99% ZrO_2, minus 100-mesh, c.i.f. Atlantic ports, per pound	.16 – .20
99+%, minus 325-mesh, c.i.f. Atlantic ports, ton lots, per pound	.45 – .60
Zirconium oxide:[3]	
Powder, commercial-reactor grade, drums, from work, per pound [3]	6.50 – 8.00
Chemically pure white ground, barrels or bags, works, per pound [3]	1.50
Electric fused, lump, bags, works, per pound	.505– .530
High-purity, bags, 98%–99% ZrO_2, works, ton lots, per pound	.63 – .80
Milled, bags, 5-ton lots, from works, per pound [3]	.64
Glass-polishing grade, 100-pound bags, 85%–90% ZrO_2, works, per pound [3]	.71
Opacifier grade, 100-pound bags, 85%–90% ZrO_2, per pound [3]	.42
Stabilized oxide, 100-pound bags, 91% ZrO_2, milled, per pound [3]	.80 – 1.10
Zirconium oxychloride: Crystal, cartons, 5-ton lots from works, per pound	.515
Zirconium acetate solution:[3]	
13% ZrO_2, drums, carload lots, from works, per pound	.22
22% ZrO_2, same basis	.38
Zirconium hydride:[3] Electronic grade, powder, drums, from works, per pound	14.50 – 16.00
Zirconium:	
Powder, per pound [5]	10.00
Sponge, per pound [2]	5.50 – 7.00
Sheets, strip, bars, per pound [2]	8.00 – 17.00
Hafnium:	
Sponge, per pound	75.00
Bar and plate, rolled, per pound	120.00
Nitrided	34.25

FOREIGN TRADE

Exports of zirconium ore and concentrate, zirconium oxide, and all forms of zirconium metal and alloys, rose in 1972 compared with the 1971 figures.

Zirconium ore and concentrate, exported to 12 countries in 1972, increased from 18,857,871 pounds valued at $801,833 in 1971 to 34,719,653 pounds valued at $940,347. The poundage of zirconium ore and concentrate exported increased 84% over that shipped in 1971, but the value rose only 17%. Both the 1972 quantity and value were alltime highs. The average value of the zirconium ore and concentrate exported in 1972, $54.17 per ton, represented a decline from the 1971 value of $85.04. This decrease is attributed to a large increase in the amount of lower cost zircon sand shipped. Exports in previous years consisted of a larger percentage of the higher cost granular and milled zircon grades. The major recipients of the exported zirconium ore and concentrate were the Netherlands, 38%; United Kingdom, 26%; Mexico, 16%; and Brazil and Canada, 9% each.

Exports of zirconium oxide increased from 1,122,741 pounds valued at $839,025 in 1971 to 1,304,352 pounds valued at $931,867 in 1972. Export quantity and value increased 16% and 11% respectively in 1972. These zirconium oxide shipments were made to 23 countries. The five major recipients in 1972 were West Germany, 26%; Italy, 13%; Canada, 12%; Brazil, 10%; and Mexico, 7%.

Total exports of other classes of zirconium increased nearly 17%, from 1,125,242 pounds in 1971 to 1,314,219 pounds in 1972. The value of this material declined 12% in 1972 to $11,508,858 from the 1971 value of $13,053,378. Of the three categories listed, only zirconium and zirconium alloy foil and leaf increased in both value and quantity in 1972. The zirconium and zirconium alloys, wrought, class increased 18% in the pounds exported but declined approximately 15% in value, and exports of zirconium and zirconium alloys, unwrought and waste and scrap, increased 11% and declined 5% in value.

Imports for consumption of zirconium ores in 1972 declined to 67,537 short tons, an almost 30% decrease from the record high of 96,387 short tons in 1971. The 1972 figure represents the smallest tonnage imported since 1968. Zirconium ore imports from the Republic of South Africa were chiefly baddeleyite (ZrO_2). The remaining zirconium ore imports were believed to be Australian zircon.

The average value of imported zircon at foreign ports increased 32% in 1972 to $46.79 per short ton, compared with $35.36 in 1971. The Republic of South Africa baddeleyite value in 1972 of $387.01 per short ton increased 21% from the 1971 value of $320.32. The tonnage imported declined 30% in 1972.

Imports for consumption of zirconium and hafnium in 1972 increased both in quantity and value in the following categories: Zirconium—wrought, zirconium waste—scrap and unwrought, zirconium compounds—n.e.c., and hafnium, unwrought—waste and scrap. Imports for consumption of zirconium declined in quantity and value in the zirconium alloys—unwrought and zirconium oxide compound classes. No wrought hafnium was imported in 1972.

WORLD REVIEW

Australia.—E. I. du Pont de Nemours & Co., has entered into a joint mining venture with Allied Minerals N.L. to process mineral sands at Eneabba in Western Australia, about 150 miles north of Perth. The newly formed mining company was named Allied Eneabba Pty. Ltd. A pilot plant was being constructed prior to a full-scale $12 million production plant scheduled for completion by 1975. The production plant is planned to produce 200,000 tons of ilmenite and 50,000 tons of rutile with additional commercial quantities of zircon, monazite, leucoxene, and kyanite.[3]

Westralian Sands Ltd. and British Titan Products Ltd. have agreed to jointly develop and exploit new reserves in Western Australia. The two companies, major ilmenite producers, were planning significant zircon production. The Mining Corp. of Australia Ltd. reported assays in the western section of the Coolyarloo Well area, also in Western Australia. The heavy mineral Coolyarloo Well deposits at a depth of 40 feet assayed 12.2% zircon and over 36% ilmenite, rutile, and leucoxene. Preliminary results from the northern area showed 12% zircon and 76% titaniferous minerals.[4]

Buka Minerals Ltd. announced plans to produce a ceramic-grade zircon from their newly acquired King Island rutile operation. The King Island operation was ac-

quired from Naracoopa Rutile Ltd. Zircon production was expected to exceed Naracoopa's old production level, 5,000 tons per year.[5] Lennard Oil Ltd. and Westralian Sands continued their joint evaluation venture of heavy mineral sand prospects north and south of Gingin near Perth. Preliminary results were said to be promising.[6]

A. V. Jennings (Jennings Industries) was proceeding alone on its 12-million-ton-per-year mineral sand project at Eneabba. A planned dry-mining operation using bucket-wheel excavators was to be carried out through a Jennings Industries subsidiary, Research and Exploration Management Pty. Ltd. Capital cost of the Eneabba project was put at $14 million.[7]

Cudgen, R. Z. Ltd., of the Union Corp. group, and its subsidiary, Consolidated Rutile Ltd., announced that they were studying the possibility of integrating their operations. The move was to offset present pressures on the weakening rutile markets.[8] Mineral Deposits Ltd. (MDL) reported increased efficiencies at its Forster processing plant, achieved by modifying the cone concentrators. This increase in efficiency was part of a company plan to more fully utilize its reserves, both low and high grade. In addition, MDL reportedly carried out several extensive and successful zircon and rutile exploration projects. Stated reserves of zircon and rutile were put at 1.2 million tons each.[9]

Brazil.—The Minegral-Companhia Brasileira de Minerações, Indústria e Commércio was recovering a high-grade zircon concentrate from its monazite beach sand processing operation.

Canada.—Eldorado Nuclear Ltd. suspended zirconium production at its Port Hope, Ontario, plant. The plant produced zirconium ingot metal and alloy for pressure tubes and fuel-cladding tubes for domestic consumption. Eldorado's unique zirconium process bypassed the conventional sponge metal step and produced ingot directly from zircon.[10]

Egypt, Arab Republic of.—Strips of natural black sand concentrates, approximately 1 kilometer wide and near 5 meters thick, containing between 5% and 7% zircon, were reported on the seashores from Al-Arish up to Marsa Matrouh. These natural black sand concentrates, carried by the Nile River to the Mediterranean Sea, were claimed to be among the world's largest known reserves.[11]

Germany, West.—Mannesmannröhren-Werke announced final plans for the completion of its plant for producing zirconium alloy tubing for nuclear reactors.[12]

Italy.—A new company partnership, Refradige S.p.A., was formed to take over production of fusion-cast refractories in Montedison's plant at San Michele all'Adige. The other partner in the new company was the French Saint Gobain group. The new company's refractories, chiefly alumina-zirconia-silica types, were intended for the glass industry.[13]

[12] Gadsen, P. Zirconium and Hafnium. Min. J., (London), June 1972, p. 94.

Japan.—Mitsui and Co., Ltd., and Teledyne's Wah Chang Albany were considering a joint company to produce zirconium metal for the Japanese market. Japanese demand for nuclear-reactor-grade zirconium tubing was expected to be 1,000 tons per year by 1975.[14]

New Zealand.—Large quantities of mineral sands were reportedly proven out by drilling along the western beaches of North and South Islands. An impact study was underway to determine the effect of this new discovery on the existing mineral sands industry and whether or not exploitation of these deposits would be to New Zealand's best interests.

Sierra Leone.—A new company, Sierra Rutile Ltd., has been formed to take over the leases of PPG Industries, Inc., and British Titan Products, Ltd., Sherbro Minerals, Ltd. Sierra Rutile Ltd. is owned by Armco Steel Corp. and Nord Resources Corp., U.S. companies, with the latter managing the mining operation. The new company was planning to produce 100,000 tons of rutile per year. The planned zircon production, although reportedly significant, was unannounced.[15]

South Africa, Republic of.—The Phosphate Development Corp. Ltd. (FOSKOR) was undergoing another expansion to fulfill the increasing demand for its unique baddeleyite concentrate. Palabora Mining Co. Ltd., mining a contiguous deposit in the Palabora igneous complex, was exploring the possibility of marketing its stockpiled baddeleyite. The baddeleyite is a coproduct from a copper and iron operation. Palabora Mining was also conducting research to further upgrade the slightly radioactive fine-grained baddeleyite into more salable products.[16]

Victor Base Minerals Corp. Ltd. and Cape Morgan Titanium Mines Corp. Ltd. were planning to begin ilmenite, rutile, and zircon production in 1973. Total zircon production from these two operations was estimated to be approximately 10,000 tons per year.[17]

General Mining and Finance Corp. Ltd., in a joint project with United States Steel Corp., reported promising assays of heavy mineral sands, containing both titanium mineralization and zircon, along the Zululand Coast.[18]

Sri Lanka (formerly Ceylon).—Ceylon Mineral Sands Corp. (CMSC), a state-owned corporation, was expanding its mineral sands operation at Pulmoddai Beach on the northeast coast. CMSC was planning a 9,000-ton-per-year increase in zircon production. CMSC put reserves of mineral sands at 3.26 million tons, averaging 80% ilmenite and rutile. The entire mineral sand production was intended for export, with Japan as the principal market.[19]

TECHNOLOGY

A Bureau of Mines study on the availability of heavy minerals as a byproduct from sand-washing plants in the Southeastern Coastal Plain States was published. Recovery of the heavy mineral fraction, chiefly rutile, ilmenite, kyanite, zircon, and monazite, citing rutile as the example, was found to be uneconomical at current market prices.[20] Experimental investigation of a laboratory-scale open-cycle vortex magnetohydrodynamic (MHD) generator at the Bureau's Pittsburgh Energy Research Center indicated that this configuration offered many advantages over straight-channel generators that require separate combustors. Compactness, lower capital cost, and high energy release were obtained by combining the combustor and generator into one unit in the vortex generators.[21] The ultra-high-temperature MHD systems use stabilized zirconia electrodes and insulator materials. In further MHD research the Office of Coal Research has contracted with the Massachusetts Institute of Technology (MIT) to assist in evaluating progress and to provide guidance in the overall government MHD-development plan (now comprising nine other contractors). MIT was advising on special investigations in the areas of high-temperature electrode materials, thermal-shock-resistant materials, and coal particle combustion.

Bureau of Mines research efforts were also directed towards determining the chlorination kinetics of zirconium dioxide and the technique of electrowinning zirconium from zirconium tetrachloride in an electrolytic cell. The former revealed that introducing carbon to the chlorinating reaction, instead of the conventional direct zirconium dioxide chlorination, resulted in reaction temperatures of approximately 800° C, or more 200° C lower than the previously used temperatures. Substitution of gaseous carbon monoxide as the reductant, in lieu of carbon, resulted in even greater efficiency.[22] The electrowinning research succeeded in plating high-purity zirconium dendrites from zirconium tetrachloride at 800° C using an electrolyte containing NaCl-NaF. The high-purity electrowon zirconium produced surpassed the American Society for Testing and Materials specifications for commercially acceptable sponge.[23] The geology, mineralogy, and economic uses of Florida heavy minerals, with emphasis on the du Pont Trail Ridge deposits at Starke and Lawtey, were related to present and future mining operations.[24]

Sodium sulfide, as a regulator, was discovered to be effective in separating monazite from zircon, by soap flotation, from the nonmagnetic fraction of selected Egyptian Mediterranean beach sand deposits.[25] The effect and the projected expanded role of cone concentrators in high-capacity mineral sand processing operations were analyzed critically.[26]

The purification of Republic of South Africa baddeleyite ores by an initial chlorinating step followed by a water leach was reported. The method involves chlorinating the finely divided ore with either carbon tetrachloride or perchloroeythlene, between 400° and 700° C, in the presence of an inert carrier gas to remove the volatile contaminating metal chlorides. The nonvolatile metal chlorides are removed by water leaching.[27] The extraction of zircon from Canadian bituminous sands by a multiple-stage flotation technique was announced. The ore slurry is first introduced into hot water, which causes the zircon and bitumen fraction to froth float. The zircon-rich froth is separated and subsequently leached with sodium hydroxide. After leaching, the zircon concentrate is removed as the zircon-rich underflow after aerating to float the solid impurities away.[28]

A thorough discussion of Australian mineral sands resources, reserves, and supply-demand position was published.[29] Recent developments including characteristics, relative economics, and applications of the two continuous-operating dredges, the hydraulic cutterhead and bucket-line ladder, were presented.[30] The dry mining and processing operations of a large Australian mineral sands producer were detailed.[31]

The preparation and chemical behavior of the hydrochlorides of zirconium oxide and its relationship to their molecular structures were discussed in detail. The zirconium hydrochlorides are intermediate compounds in the preparation of many zirconium salts.[32] Zirconium carbide-carbon composite, a promising oxidation-resistant material, was vapor-deposited directly by reacting zirconium sponge with methyl iodide[33] and/or methylene dichloride or chlorine.[34]

The preparation and thermal decomposition characteristics of zirconium- and hafnium-bearing polyester fibers for use as heat- and weather-resistant additives, as adhesives and adhesion promoters, as waterproofing and flameproofing agents for paper and textiles, and as fuel oil additives were reported during the year.[35]

Partially stabilized zirconia ceramics in the system CaO-ZrO_2 were found to be superior to conventionally prepared fully stabilized zirconia in thermal-shock properties.[36] Thermal expansion studies in the system Y_2O_3-HfO_2, from ambient temperature to 2,000° C, indicated that a stable high-temperature ceramic material can be produced by adding from 8 to 50 mole-percent Y_2O_3 to HfO_2.[37]

The AMAX Zr-Hf Newsletter[38] listed nearly 2,000 articles relating to zirconium and hafnium technology in 1972. Many of these articles were devoted to the use of zirconium and hafnium as metal alone, in alloys, and as alloying elements, not only in nuclear applications, but also in refractory and oxidation- and corrosion-resistance technology.

A comprehensive thesis on zirconium alloys, with particular emphasis on corrosion, deformation, tubing properties, and alloy development, was published. The papers listed in this thesis were presented at the International Symposium on Zirconium Alloys in Montreal, Canada, August 31, and September 1, 1971.[39] Methods for producing columbium alloy composites reinforced with TZM (titanium-zirconium-molybdenum) wire, by explosive welding techniques, were successfully developed.[40]

Materials Research Corp. announced two new techniques for producing high-purity zirconium wire, 0.002 inch thick. One technique is called the electron beam float zone refinement method, and it produces the higher purity wire in the 99.99% to 99.999% zirconium range. The other technique, electron beam melting, produces a wire of lower purity.[41]

ARSENIC[1]

Domestic Production.—Arsenic trioxide was produced in the United States as a byproduct of base-metal ores, primarily copper ore, at the Tacoma, Wash., plant of the American Smelting and Refining Company. Production figures cannot be published. Production in 1972, however, rose substantially over that in 1971 which had been curtailed by the strike at copper facilities. Shipments were less than production and yearend stocks continued the upward trend begun in 1968.

Consumption and Uses.—Apparent consumption of arsenic, essentially all as white arsenic (As_2O_3), decreased slightly from that in 1971. Calcium and lead arsenate chemicals were the major end products. Minor quantities of arsenic were used in sodium arsenate and other chemical compounds.

Production of calcium arsenate has trended downward since 1968 when nearly 1,700 tons was produced. Less than 600 tons was produced in 1969 and in 1970, and only 470 tons was produced in 1971. Lead arsenate, on the other hand, rose to nearly 3,100 tons in 1971 from 2,100 tons in 1970.

Arsenic is primarily used for its toxic qualities in the agricultural industry for insecticides, selective plant killers, defoliants, and for parasitic control in chicken feed; arsenic compounds continued to be used as wood preservatives. Consumption of Wolman Salts, the principal arsenic preservative, totaled 1,085 tons in 1971 compared with 806 tons in 1970.

About 3% of the arsenic consumed is used as metal for alloying with lead and copper. Small quantities of high-purity arsenic are used in the electronics industry.

Prices.—The price of refined white arsenic, 99.5%, at New York docks, in barrels, small lots, has been unchanged at 6-1/4 to 6-3/4 cents per pound since July 6, 1968. Refined white arsenic in bulk carload lots at Laredo, Tex., was $120 per ton, and crude white arsenic was quoted at $94 per ton at Tacoma, Wash. Lead arsenate in 50-pound bags was quoted at 26 to 29 cents per pound throughout 1972.

Arsenic metal was quoted in London at £600 nominal per long ton (64.3 cents per pound) until mid-May when it rose to £650 (69.5 cents). In July the price rose to £690 per metric ton (75.1 cents per pound) where it remained through yearend.

Foreign Trade.—No exports of arsenic metal or white arsenic have been reported since 1945.

Imports of white arsenic declined 21% in 1972 to 13,600 tons, the lowest level since 1960. Sweden, the principal supplier of white arsenic, furnished 60%, followed by Mexico with 26%, and France with 11%.

---

[1] Prepared by Gertrude N. Greenspoon, mineral specialist.

Receipts of arsenic metal were 665 tons, 24% more than in 1971. Sweden supplied 659 tons, Canada 5 tons, and Japan 1 ton. Small quantities were received from Belgium-Luxembourg, West Germany, the Netherlands, and the United Kingdom.

Tariff.—Under the General Agreement on Tariffs and Trade (GATT), the duty on arsenic metal was reduced from 1.5 to 1.2 cents per pound, effective January 1, 1972. Arsenic oxide (white arsenic) enters duty free.

World Review.—*Brazil.*—All white arsenic produced in Brazil is recovered as a byproduct from the treatment of gold ore produced at the Morro Velho mine near Belo Horizonte. The mine is operated by Mineração Morro Velho, S.A. Peak output was attained in 1951 when 1,500 tons was produced. Thereafter, production trended downward to 181 tons in 1972.

France.—Two processing plants, one each in the Aude and Bouches du Rhône Departments, account for all white arsenic produced in France. About half of the output is derived from arsenical pyrite produced in Aude and the remainder comes from the treatment of imported ores.

Sweden.—The Boliden Co. will build a new plant for the production of arsenic metal.[2] The plant located at the company Rönnskär works will have an initial capacity of 1,500 tons annually and is estimated to cost $2 million. A new process developed by Boliden, which will be utilized, is said to be virtually continuous, will provide a good working environment, and will create no pollution. All production units will be equipped with closed ventilation systems. Ventilation air and process gases will be treated in wet scrubbers and the scrub water will be highly purified before disposal.

Technology.—In a study[3] conducted on methods for removing arsenic from gold extraction plant effluents, the chemical precipitation process was considered to be effective and the most attractive from an economic standpoint. Two other methods—ion exchange resins and activated charcoal adsorption, and reverse osmosis—were alternative choices also investigated.

[e] Estimate. [p] Preliminary. [r] Revised. W Withheld to avoid disclosing individual company confidential data.

[1] Including calculated trioxide equivalent for output reported as elemental arsenic and arsenic compounds other than trioxide.

[2] In addition to the countries listed Argentina, Austria, Belgium, the People's Republic of China, Czechoslovakia, East Germany, Finland, Hungary, Southern Rhodesia, the United Kingdom and Yugoslavia have produced arsenic and/or arsenic compounds in previous years, but information is inadequate to ascertain whether such production has continued, and if so at what levels.

[3] Output of Tsumeb Corp. Ltd. for year ending June 30 of that stated; data given are white arsenic equivalent of reported black arsenic oxide production.

Background data for the study disclosed that the arsenic dissolved in the final plant effluent discharged to the lake constituted only 0.3% of the arsenic contained in the mill feed. Distribution of the remainder of the mine arsenic balance was 14.8% in solids discharged to the lake, 2.6% in mine backfill, 1.8% in roaster flue dust, and 80.5% (by difference) in roaster stack losses.

CESIUM AND RUBIDIUM [4]

Domestic Production.—No cesium or rubidium ores were produced in the United States in 1972. Imported pollucite and *ALKARB*, a residue from past lithium compound production, were the raw material sources for all domestic production of cesium and rubidium products.

The total production of the chemical compounds of cesium declined in 1972 while the production of rubidium compounds increased. Compounds were produced by Cooper Chemical Co., Long Valley, N.J.; Kawecki Berylco Industries, Inc. (KBI), Revere, Pa.; Kerr-McGee Corp., Trona, Calif.; and Rocky Mountain Research, Inc., Golden Colo. No rubidium metal and only a few pounds of cesium metal were produced during the year. KBI and MSA Research Corp., Evans City, Pa., shipped both metals from inventories.

Consumption and Uses.—Statistics on the consumption and uses of cesium and rubidium metal and compounds were not available. The largest use was probably in research and development of new power generating systems, the biological sciences, and other technical fields. Commercial applications for cesium and rubidium included their use in pharmaceuticals, scintillation counters, photomultiplier tubes, photoelectric cells, ultracentrifuges, and ionic propellant engines for space-flight applications. Cesium and rubidium and their compounds can be substituted for each other in some uses.

The development of commercial-scale magnetohydrodynamic (MHD) electric power generators and thermionic converters appeared to offer the greatest potential for large usage of cesium and rubidium. Research on MHD received increased funding both privately and through the Office of Coal Research, U.S. Department of the Interior. If successfully developed, MHD was expected to provide cheaper electricity and major increases in power generating efficiency. Investigations have indicated that a mixed potassium-cesium seeding is

desirable for open-cycle MHD coal-burning power plants.[5]

Prices.—American Metal Market quoted a nominal price for pollucite (about 20% Cs) over 10 tons, delivered entry point, at $300 per short ton. Metal Bulletin quoted a nominal price for pollucite concentrates, minimum 24% Cs_2O, f.o.b. source, at $12.40 (using 1£ = $2.60) per metric ton unit (22.046 pounds) of Cs_2O. The American Metal Market quotation on cesium metal 99+% was unchanged at $100 to $375 per pound. The quotation on rubidium metal, 99.5+%, was also unchanged at $300 per pound.

Foreign Trade.—Pollucite was imported from Canada during 1972, but data on quantities and values of imports of cesium and rubidium raw materials were not published. Imports of cesium compounds increased to over 12,000 pounds nearly three times the quantity in 1971. Rubidium metal was not imported during 1972. No other data were available on imports and exports of cesium and rubidium products.

Table 5.—U.S. imports for consumption of cesium compounds, by country

Country	Cesium chloride		Cesium compounds, n.s.p.f.	
	Pounds	Value	Pounds	Value
Germany, West	1,661	$56,934	8,358	$252,328
Netherlands	--	--	1,974	20,078
United Kingdom	--	--	55	1,351
Total	1,661	56,934	10,387	273,757

World Review.—In 1971, Tantalum Mining Corp. of Canada, Ltd., produced about 400 tons of pollucite at its mine at Bernic Lake, Manitoba. The company did not mine pollucite in 1972, but shipments were made from stocks.

GERMANIUM [6]

The short supply situation reversed itself in mid-1970 when semiconductor demand dropped by an estimated 50% resulting in excessive consumer stocks and an oversupply of germanium for a brief period of 1 to 1½ years. Demand has increased since the 1970 slump with a slow and steady growth in both the semiconductor and optical industry. Estimated production of germanium from primary and secondary sources for 1972 was the same when compared to 1971.

Legislation and Government Programs.—Information was received on August 21, 1972, that germanium point contact diodes from Japan were being sold at less than fair value within the meaning of the Antidumping Act, 1921, as amended. This information was the subject of an "Antidumping Proceeding Notice" which was published in the Federal Register, September 23, 1972, page 20046. The notice indicated that there was evidence on record concerning injury to or prevention of establishment of an industry in the United States.

Domestic Production.—Production of primary germanium from domestic raw material sources was estimated at 27,000 pounds in 1972, with an additional estimated 10,000 pounds recovered from germanium-containing zinc concentrates imported from other countries. Most of the primary germanium was obtained from treating smelter residues resulting from the processing of roasted zinc concentrates. No mines are operated solely for recovery of germanium. This metal is a minor byproduct of ores mined for zinc with the supply of germanium being a function of the zinc production rate. Although at present no new residues are derived from treating ores of the Kansas-Missouri-Oklahoma region or from Kentucky and Illinois, a significant supply of residues has been stockpiled. Primary production was supplemented with recycled waste or new scrap. Waste recycle returns from 65% to 80% of the metal as scrap from cutting shapes used in the manufacture of semiconductors. Eagle-Picher Industries, Inc. of Miami, Okla., was the only producer of primary germanium from domestic sources. The above company and others listed below produced germanium from secondary sources and imports: GTE Sylvania, Towanda, Pa.; Kawecki Berylco Industries, Inc., Revere, Pa.; and Atomergic Chemetals Co., Long Island, N.Y.

---

[5] Bergman, P. D., and D. Bienstock. Economics of Mixed Potassium-Cesium Seeding of an MHD Combustion Plasma. BuMines RI 7717, 1972, 12 pp.

[6] Prepared by Herbert R. Babitzke, physical scientist.

Consumption and Uses.—The principal form in which germanium is used for semiconductors is as high-purity single crystal metal while for optical applications the material must be of high purity but may be polycrystalline. Semiconductor devices account for a large portion of the domestic demand. Electronic components account for 55% of the current use of germanium, and the remaining 45% is consumed in the manufacture of specialized optical glass, infrared equipment, and other minor applications. Germanium and silicon transistors, diodes, and rectifiers have replaced vacuum or electron tubes in many applications where cost-performance ratios have been competitive and where miniaturization is necessary in solid state devices. A market for germanium will continue to exist in those semiconductor applications where it is more reliable than silicon, specifically in some high-frequency and high-power requirements.

Germanium has numerous miscellaneous applications including nuclear radiation detectors, in solder and brazing alloys, as an alloying constituent to improve the mechanical properties of copper, aluminum, and magnesium alloys, in thermistors, photoconductors, and superconductors. Germanium has a high refractive index and is transparent to infrared light. To take advantage of this unique property, germanium windows, prisms, or lenses are employed in various optical systems.

Research is continuing in a number of areas which employ germanium. A large part of the research was to establish more of the physical constants of germanium and various germanium alloys and compounds.

A significant contribution was made to the petroleum refining industry when a new series of petroleum catalysts were developed. In the bimetallic cat-cracking catalysts platinum is one of the components and the second metals considered were gold, gallium, germanium, indium, and iridium.[7] A patent was issued to Universal Oil Products Co., Des Plaines, Ill., concerning a novel catalytic composite.[8] The catalyst comprised a combination of a platinum-group component, a germanium component, and a halogen component with a porous carrier material to result in a composite containing 0.01 to 2.0 weight-percent platinum, 0.01 to 5.0 weight-percent germanium, and 0.5 to 3.5 weight-percent halogen. The principal use of the composite was in the conversion of hydrocarbons, particularly in the reforming of a gasoline fraction. This catalyst had exceptional activity, selectivity, and resistance to deactivation when employed in a hydrocarbon conversion process that requires a catalyst having both a hydrogenation-dehydrogenation function and an acid function.

Highly refined germanium is one of the keys to making an X-ray spectrometer used for measuring the lead content of ordinary steels. The lead content is a gage of machinability. The spectrometer, the first of its kind in industry was placed in operation in a steel plant in September 1972. The instrument operates through X-ray fluorescence analysis, using cobalt as the radioactive source. When the steel sample is exposed to the high-energy X-rays from the radioisotope, the lead particles become fluoresced or energized. The fluoresced lead X-rays are then counted by the unit's germanium transducer, and digital electronics provides the necessary energy analysis.

---

[7] Burke, Donald P. A Comprehensive Look at a $168-million/year Business Headed for Spectacular Growth. Part 1: Petroleum Catalysts. Chem. Week, v. 111, No. 18, Nov. 1, 1972, pp. 23–33.

[8] Hayes, John C. Hydrocarbon Conversion Process and Platinum-Germanium Catalytic Composite for Use Therein. U.S. Pat. 3,578,584, May 11, 1971.

Prices.—The price of domestic zone-refined (intrinsic) germanium was $293 per kilogram and germanium dioxide was $167.50 per kilogram. These prices have been in effect since June 8, 1970. At the beginning of the year, imported germanium and germanium dioxide was $207 and $108.50 per kilogram, respectively, effective since January 1, 1971, but on April 1, 1972, the prices of imported germanium and germanium dioxide were increased to $229 and $120 per kilogram, where they remained through the end of the year.

Foreign Trade.—U.S. imports of germanium metal (unwrought, and waste and scrap) was 5,506 pounds valued at $724,331, a decrease from the previous year of 17% in quantity and 30% in value. The U.S.S.R. supplied 54% of the germanium imports. Belgium-Luxembourg supplied only 10% of the germanium but this represented 63% of the total value.

World Review.—World production of primary germanium was estimated at 160,000 pounds for 1972 which was 7% more than in 1971. Production in Japan was 49,395 pounds of germanium and 27,192 pounds of germanium dioxide. Japan also imported 593 pounds of germanium metal and 44,536 pounds of germanium dioxide. All African production of germanium was from the Shaba and Kivu Provinces of Zaire. In 1971, 117,000 pounds of germanium was produced by La Générale des Carrierès et des Mines du Zaire (Gécamines) a Zairian government company under contract with the Société Générale des Minerais of Belgium. Refining was done in Belgium.

Table 6.—U.S. imports for consumption of germanium, by country

Country	Quantity	Value
	Unwrought, and waste and scrap	
Belgium-Luxembourg	544	$455,401

Belgium-Luxembourg	13	3,134
Denmark	102	10,000
Switzerland	289	20,442
Total	404	33,576

INDIUM[9]

Domestic Production.—The American Smelting and Refining Company was the only domestic producer of indium during the year. Refining plants were situated in Denver, Colo., and Perth Amboy, N.J. Indium was recovered from flue dusts and residues in which indium source materials were concentrated during the processing of zinc ores and concentrates.

Uses.—The chief use of indium was in various applications in the manufacture of electronic devices. It was used as a component of solder for connecting lead wires to germanium in transistors and as a property-modifying agent in intermetallic germanium semiconductors. Indium compounds (arsenides, antimonides, and phosphides) were used in various electronic applications; indium halides were used as a color correctant in mercury vapor lamps. Indium-containing alloys were used in glass-sealing, and in dentistry.

Stocks.—Despite increased imports, stocks were estimated to have decreased.

Prices.—Producer prices of indium during the year were unchanged at $2.50 per troy ounce for sticks in lots of less than 100 ounces; ingots of 100 ounces brought $2.05 per ounce and lots of 10,000 ounces were priced at $1.75 per ounce. Probably very little metal moved at $1.75 as the dealer's price was in the range of $1.20 to $1.40 per ounce in ingot lots. Metals Week started quoting ingots at $1.75 effective December 14, 1972, and ceased quoting sticks.

Foreign Trade.—Imports of indium rose 62% over 1971 imports to 628,887 ounces. The lower world price of the material accounted for the growth of imports, because foreign metal could be traded by dealers for more than $1.00 per ounce less than the domestic producer price. The chief sources of imports were: Canada, 33%; U.S.S.R., 27%; Peru, 15%; United Kingdom, 14%; and others, 11%.

---

[9] Prepared by Burton E. Ashley, physical scientist.

In accordance with decisions made under the General Agreement on Tariffs and Trade, the import duty on unwrought, waste and scrap metal was 5% ad valorem for 1972; however, such duties were temporarily suspended until June 30, 1973, under Public Law 92-44 which was effective June 30, 1971. Wrought metal was dutiable at a rate of 9% ad valorem and indium compounds at 5% ad valorem. The statutory rate on unwrought, waste and scrap metal, and on compounds, remained at 25% ad valorem from Communist-bloc countries; the duty on wrought metal was 45% from Communist-bloc countries, with Yugoslavia excepted in both cases.

Table 7.—U.S. imports for consumption of indium, by country

Country	Quantity (troy ounces)	Value
	Unwrought, waste and scrap	
Canada	209,928	$216,781
Germany, West	44,440	51,599
Japan	18,452	92,606
Netherlands	5,449	10,165
Peru	94,104	144,461
U.S.S.R	170,242	281,850
United Kingdom	85,185	118,478
Total	627,800	910,885
	Wrought	
Netherlands	1,087	1,373

RADIUM[10]

During 1972, radium was used primarily in therapeutic treatment of cancer. There were fewer industrial applications as substitution by cheaper and less hazardous radioisotopes continued.

Legislation and Government Program.—During 1972, there were no specific Federal programs related to radium only. Radium was not held in Governmental stockpiles. Imports of radium and its compounds were free of tariff.

Domestic Production.—Radium has not been produced in the United States for many years. The small domestic requirements were met by imports or withdrawal from dealers' stocks. The Belgian company, Union Minière S.A., remained the principal source of imported radium during 1972. Radium Chemical Co., Inc., New York, was the main radium dealer in the United States during 1972.

Uses.—Radium, in small quantities expressed in milligrams, was used in treatment of cancer and in luminous compounds, static eliminators, and neutron sources. Based on manufacturers' sales data, about 1,300 to 1,600 curies[11] of radium have been sold in the United States to date. Approximately 330 to 360 curies of radium, contained in 50,000 to 60,000 sources, were used in medical applications. Nonmedical uses accounted for 250 curies, and the rest was involved in luminous compounds and other uses.[12]

Up to 40 curies are added annually to the totals of radium in use in the United States. The after-effects of gamma radiation in medical applications and the price of radium have lead to substitution by other radioisotopes. This trend was also apparent in other uses of radium.

Prices.—Radium prices, per milligram, were quoted by Radium Chemical Co., as follows: Less than 100 milligrams, $24; 200 to 499 milligrams, $20; 500 milligrams to 4.99 grams, $18; over 5 grams, $17.

World Review.—Information on radium in world markets is not readily available, mainly because of the small quantities involved in production and trade. Small amounts of radium and its compounds are produced in Belgium, Canada, the United Kingdom, and the U.S.S.R. Trade in radium was not published as such; in most cases, radium is included with other items in trade statistics.

Technology.—The Federal Bureau of Mines continued a study to develop techniques for recovering radium from uranium ores, tailings, and processing solutions to eliminate this radioactive contaminant. Leaching of uranium ores with hydrochloric acid resulted in extraction of 20% to 90% of contained radium. During 1972, samples of domestic uranium ores and uranium mill tailings were examined. Results confirmed fair recovery of radium. In case of increased future demand, this method could become a new source of radium.

---

[10] Prepared by Roman V. Sondermayer, physical scientist.

[11] One curie is equivalent to radioactivity of 1 gram of pure radium, or 3.7 × 10 disintegrations per second.

[12] Data on uses are estimates based on partial sales reports.

SCANDIUM [13]

Production of scandium metal, measured in grams, increased slightly compared with that of 1971. Scandium was used mostly in reasearch and in production of high-intensity lamps. The main potential raw material source for scandium was waste products from uranium mills although none was recovered in 1972. The bulk of domestic demand apparently was met by imports. Trade in scandium was not reported as such, but was included with other items in trade statistics.

Domestic Production.—Research Chemicals, a division of Nucor Corp., Phoenix, Ariz., was the only domestic producer of scandium during 1972. Supply was adequate for the small demand. The limited consumption and high production costs were expected to maintain high prices for marketable scandium products. Extraction of scandium from other sources, such as phosphate rock and tungsten concentrate, was not considered profitable.

Uses.—In addition to uses in research and development, scandium had two commercial applications. High purity scandium metal was used in the manufacture of high-intensity mercury lamps. These lamps were particularly useful for illumination of events televised in color because their illuminating efficiency and color range approached the qualities of sunlight. Radioisotope scandium-46 was used in tracing fluid flows in oil well reservoir studies and in evaluation of quality of casing cementations.

Prices.—The price of scandium oxide, 99.9%, as quoted by Research Chemicals, remained unchanged during the year at $2.80 per gram in lots of 100 to 453 grams; that of scandium metal in ingots and distilled forms was $8 and $15 per gram, respectively, while that of powder and chips remained unchanged at $10.35 per gram. Prices for scandium sheet foil were $17.85 to $105 per square inch for 51 to 100 square inch lots, ranging from 0.001 to 0.1 inch in thickness. Larger quantities were available for most items at lower prices.

Technology.—Most research remained aimed at a better understanding of properties and behavior of scandium in different environments. A limited number of projects were related to production of scandium metal and compounds. A process for recovering scandium from uranium waste liquors was developed using a three-phase system of an ion exchange resin, H_2SO_4 solution, and kerosene solution of bis (2-ethyl-hexyl) phosphate. Distribution of scandium in the system was tabulated. Selective scandium desorption is possible using this method.[14]

SELENIUM [15]

Domestic selenium production was 769,000 pounds, an increase of 17% from 1971. Shipments by domestic producers increased 19% to 791,000 pounds with the difference supplied from stocks which stood at 161,000 pounds at yearend. World production increased 5% to 2,642,000 pounds.

On August 11, 1971, Congress authorized disposal of the 474,774 pounds of selenium held in the national stockpile. No disposals were made during the remainder of 1971. During 1972 a total of 16,090 pounds of selenium was sold or exchanged for strategic commodities needed for the national stockpile.

Domestic Production.—Primary selenium was produced at four plants operated by the following major electrolytic copper refiners: American Metal Climax, Inc., Car-

[1] Includes an estimated 30,000 pounds of selenium refined from secondary sources.

teret, N.J.; American Smelting and Refining Company, Baltimore, Md.; The Anaconda Company, Perth Amboy, N.J.; and Kennecott Copper Corp., Garfield, Utah. Crude materials containing primary selenium were transferred to these plants from copper refineries operated by Inspiration Consolidated Copper Co., Magma Copper Co., and Phelps Dodge Corp. An estimated 30,000 pounds of selenium was recovered by domestic secondary refineries from purchased electronic scrap. Considerable selenium home scrap was reused by manufacturers after outside reprocessing under toll contracts. Some domestic selenium-containing material was shipped to foreign plants for refining. High-purity selenium and various selenium compounds were produced by primary and other processors from commerical grade metal.

Consumption and Uses.—Apparent selenium consumption increased about 10% from 1971. Estimated usage in glass manufacturing, which consumed over one-third of the total metal used, increased over 15%. Small proportions of selenium compounds are added to glass melts to neutralize the green coloration caused by iron. Larger proportions are used to produce gray and bronze tinted window glass that reduces glare and heat transmission and to produce red- and amber-colored glass for signals and decorative uses. Consumption of selenium in xerography increased slightly during 1972 and this use now consumes about one-fourth of the primary metal shipped. More efficient use of selenium in xerographic copying machines and reclaiming of home scrap have restrained the consumption of primary selenium in xerography despite increasing use of copying machines. However, new applications in this field promise a larger future demand. Selenium consumption for rectifiers, photoelectric cells, and other electronic applications remained steady despite industry expansion, because of more efficient usage of selenium. Electronic uses consumed about one-fifth of the selenium marketed. Demand for selenium in pigments and steel alloys increased significantly. Other chemical, pharmaceutical, and miscellaneous uses were little changed from 1971.

Prices.—The producers' price for commercial and high-purity-grade selenium remained at $9 and $11.50 per pound, respectively, throughout the year, but there were periods of spot shortages and surpluses of metal. The merchant price for commercial grade was $9 to $9.30 during early 1972, slumped to below $8 in August and recovered to about $8.40 in November, and was $9 at yearend.

Foreign Trade.—Selenium exports rebounded from 1971 shipments which were unusually low because of the copper industry strike. The largest shipments were made to West Germany, the United Kingdom, and the Netherlands.

Selenium imports for consumption increased 9% and the value of imports increased 4%. Canada continued to be the principal supplier. Imports by country are shown in table 9.

World Review. The United States was the leading selenium producer, Japan was second, and Canada was third. These three countries accounted for 82% of world production (excluding the U.S.S.R.).

Technology.—The Selenium-Tellurium Development Association, Inc. continued sponsorship of research programs designed to increase selenium utilization.

United States animal feed processors have applied to the Food and Drug Administration for approval to add selenium to feed for poultry and swine. Research on animal nutrition has shown that, although food containing more than 3 parts per million (ppm) of selenium can be poisonous to swine and poultry, concentrations of up to 0.1 ppm are beneficial to swine and chickens and up to 0.2 ppm are beneficial to turkeys. Farm and laboratory animals whose diets are deficient in selenium are susceptible to serious disorders including muscular dystrophy and necrosis of the liver, kidneys, and pancreas. Selenium deficiency also makes animals highly vulnerable to poisoning from heavy metals such as mercury and lead. Selenium feed additions have long been used with good effect in Australia and New Zealand where the soil is notably lacking in selenium. The selenium content of U.S. soil varies considerably, ranging from dangerously high to inadequate. Studies are also in progress to determine optimum human selenium consumption and the present intake from food, air, and water.

[e] Estimate. [p] Preliminary. [r] Revised.

[1] Insofar as possible, data relate to refinery output of elemental selenium only; thus countries that produce selenium in copper ores and concentrates, blister copper, and/or refinery residues, but do not recover elemental selenium have been excluded to avoid double counting.

[2] In addition to the countries listed, West Germany and the U.S.S.R. are known to produce refined selenium and Zaire and Zambia may produce refined selenium, but available information is inadequate to make reliable estimates of output levels.

[3] Exports.

[4] Recoverable selenium content of blister copper treated at domestic refineries plus refined selenium from domestic raw materials, but excludes other unspecified materials that provide a portion of total refined selenium output. Corresponding figures for previous years in thousand pounds are: 1970—668; 1971—719.

[5] Figures represent mine output only, not refinery production.

TELLURIUM[16]

Domestic tellurium production of 257,000 pounds was the highest since 1962 and was 57% above the strike-reduced output of 1971. Domestic shipments of 271,000 pounds was a new record. Imports increased five times from those of 1971.

Domestic Production.—Production of tellurium was reported by the following major electrolytic copper or lead refiners: American Metal Climax, Inc., Carteret, N.J.; American Smelting and Refining Company, Baltimore, Md.; The Anaconda Company, Perth Amboy, N.J.; and United States Smelting Lead Refinery, Inc., East Chicago, Ind., division of UV Industries, Inc. Electrolytic refinery sludges containing primary tellurium were also produced at refineries operated by Inspiration Consolidated Copper Co., Kennecott Copper Corp., Magma Copper Co., and Phelps

---

[16] Prepared by Lyman Moore, mining engineer.

Dodge Corp. High-purity tellurium, tellurium master alloys, and tellurium compounds were produced by primary and intermediate processors from commercial-grade metal and tellurium dioxide.

Consumption and Uses.—Tellurium shipments for use as a free-machining agent in carbon and stainless steel and as a chilling agent in cast iron increased from the previous year and were about 60% of the total consumption. Reductions in consumer inventories that held down shipments in 1971 were completed and steel makers and machinery manufacturers increased purchases especially in the later part of the year. Consumption of tellurium in free-machining copper increased and was about 20% of consumption. About 11% was used in rubber manufacture, 6% in chemicals, and 3% in electronic and other uses.

Prices.—The producer price for commercial-grade powder and slab continued at $6 per pound throughout 1972, unchanged since 1962. Some discounting by merchants was reported during the first part of the year. Prices for high-purity grades of tellurium ranged from $10 to $32 per pound.

Table 12.—U.S. imports for consumption of tellurium, by country

(Thousand pounds and thousand dollars)

Country	Quantity	Value
Canada	15	100
India	(1)	2
Peru	131	713
Total	146	815

[1] Less than ½ unit.

Foreign Trade.—Imports in 1972 were 146,000 pounds compared with 30,000 pounds in 1971. Large shipments were received from Peru early in the year. The imported metal was nearly all of commercial grade and had an average value of $5.58 per pound. In accordance with the General Agreement on Tariffs and Trade, the effective import duty was reduced January 1, 1972, from 4.5% ad valorem on metal and 6.0% ad valorem on compounds to 4% and 5%, respectively.

World Review.—The United States continued to lead the world in tellurium output; Japan was second and Canada third.

Table 13.—Tellurium: World refinery production by country [1]

(Thousand pounds)

Country [2]	1970	1971	1972 [p]
Canada	[r] 65	44	[3] 48
Japan	78	79	77
Peru	[r] 66	53	[e] 40
United States	158	164	257
Total	[r] 367	340	422

[e] Estimate. [p] Preliminary. [r] Revised.

[1] Insofar as possible, data related to refinery output only, thus countries that produce tellurium in copper ores and concentrates, blister copper, and/or refinery residues, but do not recover refined tellurium are excluded to avoid double counting.

[2] In addition to the countries listed, Australia, Belgium, West Germany and the U.S.S.R. are known to produce refined tellurium, and other countries such as Zaire and Zambia may produce refined tellurium, but available information is inadequate to make reliable estimates of output levels.

[3] Includes recoverable tellurium content of blister copper treated at domestic refineries plus refined tellurium from domestic raw materials but excludes other unspecfied materials that provide a portion of total refined tellurium output. Corresponding figures for previous years in thousand pounds are: 1970—59; 1971—24.

THALLIUM[17]

Thallium and thallium compounds are limited as to both size of market and number of uses. Federal restrictions regarding use of some compounds deter the use of this rare metal.

Domestic Production.—The American Smelting and Refining Company, Denver, Colo., was the only domestic producer of thallium and thallium compounds. Metal production was up slightly over 1971, but shipments were down.

Uses.—Distribution of thallium consumption was about 40% for electronics, 30% for low-melting alloys, 10% for optical glass, 7% for agriculture, 3% for medicine, 5% for academic purposes and development research, and other uses about 5%.

Curtailment of thallium as a rodenticide by Government action is continuing with increasing controls resulting from an accidental killing of wildlife in 1971 in the West. On February 8, 1972, the President issued Executive Order 11643 which offers environmental safeguards on activities for animal damage control on Federal Lands. The policy of the order is to restrict the use of chemical toxicants for killing predatory mammals, birds, or reptiles, which may cause secondary poisoning of such animals on Federal Land, and the use of such toxicants in any Federal program of mammal or bird damage control.

Thallium has a significant use in the electronics industry for production of thallium-activated sodium iodide crystals and for the production of "thallofide" cells which contain thallium sulfide and are sensitive to infrared radiation. Some thallium compounds are extremely photosensitive especially to light of low intensity. Thallium is also used in low-melting alloys for switches, thermometers, and other instruments for protection against extreme Arctic temperatures. Further use of thallium is likely for reaction intermediates in a variety of syntheses where the oxidizing power of thallium (III) and the stability of thallium (I) derivatives are exploited.[18]

Prices.—The price of thallium in 25-pound lots has been $7.50 per pound since December 1957.

Foreign Trade.—U.S. imports for consumption in 1972 were 1,449 pounds of unwrought, and waste and scrap thallium valued at $3,940. The amount was about twice that imported in 1971. Thallium compounds imported were 936 pounds valued at $7,144.

Table 14.—U.S. imports for consumption of thallium in 1972, by country

Country of origin	Compounds (gross weight)		Unwrought, and waste and scrap	
	Pounds	Value	Pounds	Value
Belgium-Luxembourg	425	$1,468	1,000	$2,910
Canada	--	--	3	259
Germany, West	246	2,567	--	--
U.S.S.R.	--	--	446	771
United Kingdom	265	3,109	--	--
Total	936	7,144	1,449	3,940

GREENSAND [1]

Greensand (glauconite, essentially a hydrous silicate of iron and potassium) was produced in 1972 only by Inversand Co., Clayton, N.J. Production and sales data are withheld to avoid disclosure of company confidential data. However, it may be of interest to know that the average annual production for the period 1967 to 1971 was 3,437 tons valued at $233,000. During this period, there were two producers of greensand.

Greensand was used by various water treatment manufacturers.

A cooperative agreement between the Bureau of Mines and the Delaware State Geological Survey to sample and evaluate Delaware greensand for potential uses was continued. Forty samples of greensand were analyzed and the results were being evaluated for additional work.

IODINE [2]

Consumption of crude iodine did not change appreciably from that of 1971, but there was a surplus for most of 1972. Industry stocks were particularly high in early 1972 because of record tonnages of iodine imported during the previous year in anticipation of higher prices. Domestic output which represented a small part of overall supply, increased somewhat compared with 1971, whereas imports declined by more than 1 million pounds.

Crude iodine production in the free world rose by possibly 700,000 pounds, or 3 to 4 percent, almost all accounted for by Japan, which more than made up for the slight decline in output by Chile, the world's second ranking iodine producer. Japanese iodine was priced at $1.86 per pound all year and Japan was the sole supplier of iodine to the United States. On the other hand, Chile was selling at $2.27 and, in effect, temporarily priced itself out of the U.S. market. Domestic iodine was also quoted at $2.27, but this did not cause difficulties in marketing, since the iodine was converted into downstream products before sale. At yearend, pressure was being built up for another round of upward evaluation of the Yen, which in turn would mean higher prices for Japanese iodine.

Legislation and Government Programs.—On December 31, 1972, the Government strategic stockpile contained 2,955,692 pounds of crude iodine, and the supplemental stockpile, 5,056,122 pounds for a total of 8,011,814 pounds. The stockpile objective for iodine, established by the Office of Emergency Preparedness, was reduced from 8 million to 7.4 million pounds in October. However, there were no stockpile withdrawals or deliveries of iodine in 1972.

Table 1.—Crude iodine consumed in the United States

Products	1971			1972		
	Number of plants	Crude iodine consumed		Number of plants	Crude iodine consumed	
		Thousand pounds	Percent of total		Thousand pounds	Percent of total
Resublimed iodine	5	W	W	6	600	11
Potassium iodide	6	1,612	34	10	1,514	29
Sodium iodide	4	W	W	4	90	2
Other inorganic compounds	15	1,209	25	14	983	19
Organic compounds	21	1,980	41	19	2,071	39
Total	[1] 34	[2] 4,802	100	[1] 30	[2] 5,258	100

W Withheld to avoid disclosing individual company confidential data; included with "Other inorganic compounds."

[1] Nonadditive total because some plants produce more than one product.

[2] Data may not add to totals shown because of independent rounding.

Depletion allowance for domestic iodine producers was changed under terms of the Tax Reform Act of 1969. Effective with taxable years beginning after October 9, 1969, the depletion allowance for iodine from both domestic and foreign production is 14 percent of gross income, not to exceed 50 percent of net income without the depletion deduction.

Domestic Production.—The Dow Chemical Co., the only domestic producer, recovered crude iodine from well brines at Midland, Mich. as a coproduct with bromine, calcium, and magnesium compounds. Compared with that of 1971, quantity of output increased by approximately 3 percent, and value, 12 percent.

Consumption and Uses.—Based upon returns from questionnaires, approximately 5.26 million pounds of crude iodine was consumed by 30 firms in 12 States. Leading iodine-consuming States in 1972, in descending order of magnitude, were Missouri, New York, New Jersey, and Pennsylvania, which together accounted for more than four-fifths of the total crude iodine consumption.

The above information is indicative of the consumption pattern but is not necessarily completely comprehensive. Iodine and iodides employed as catalysts and in "dissipative" uses in general, particularly in making synthetic rubber, are not well covered. Imports alone have been consistently higher than reported consumption, with net differences as follows, in thousand pounds: 1970, 981; 1971, 2,473; and 1972, 949. A more exact estimate of apparent consumption cannot be published as U.S. production figures for crude iodine cannot be revealed.

Iodine consumed in making immediate downstream products, such as resublimed iodine, potassium iodide, sodium iodide, and organic iodine-containing compounds, have not shown any radical changes in recent years. As for ultimate downstream uses, the major categories in 1972 were roughly as follows, in order of descending importance: catalysts (in rubber), food supplements, stabilizers (in nylon), inks and colorants, pharmaceuticals, sanitary uses, and photographic uses.[3] Iodine was also consumed in making high-purity metals, motor fuels, iodized salt, smog inhibitors, swimming pool sanitizers, and lubricants.

Prices.—There were very few price changes in 1972, although by yearend higher prices were imminent for Japanese iodine, which eventually went up to $2.06 per pound around mid-February 1973. U.S. and Chilean iodine were quoted at $2.27 all year. As usual, prices had little to do with supply and demand, since an oversupply situation was accompanied by high prices. Quoted prices for iodine and iodine compounds at yearend 1972 were as follows, per pound.

	Per pound
Crude iodine, drums	$1.86–$2.27
Resublimed iodine, U.S.P., drums, f.o.b. works	3.97– 4.00
Calcium iodate, drums, delivered	2.50– 2.80
Calcium iodide, 35-pound drums, f.o.b works	5.98
Potassium iodide, U.S.P., crystals, drums, 300 to 999 pounds, delivered	2.60– 2.95
Potassium iodide, U.S.P., crystals, drums, smaller lots, delivered	2.75– 2.95
Sodium iodide, U.S.P. crystals, 300-pound drums, freight equalized	3.50– 3.63

[3] Chemcial Marketing Reporter (New York). V. 203, No. 10, Mar. 5, 1973, pp. 3 and 23.

Foreign Trade.—Crude iodine imported into the United States in 1972 declined by nearly 15 percent in quantity compared with that of 1971, but total value decreased only 12 percent. The average value of imported crude iodine rose from $1.58 per pound in 1971 to $1.64 per pound in 1972. About 6.2 million pounds of crude iodine was imported, all from Japan. Imports of resublimed iodine were nominal compared with imports of crude iodine.

Tariff rates remained at 5 cents per pound on resublimed iodine and 12 cents per pound on potassium iodide. Crude iodine enters the United States duty free.

Table 2.—U.S. imports for consumption of crude iodine, by country

(Thousand pounds and thousand dollars)

Country	1970		1971		1972	
	Quantity	Value	Quantity	Value	Quantity	Value
Chile	1,723	2,076	2,950	5,679	--	--
Japan	4,320	4,758	4,325	5,831	6,207	10,184
Total	6,043	6,834	7,275	11,510	6,207	10,184

World Review.—*Chile.*—Production of crude iodine in 1972 as a byproduct of nitrates probably was just under 2,500 short tons. Output was on the low side for Chile, but even the upper limit would not be much more than 3,000 short tons per year because of limitations related to extraction of coproduct nitrates.

Chile's three iodine plants owned by Sociedad Química y Minera de Chile, S.A. (SOQUIM), namely Valdivia, Victoria, and Elena, were operated nearly full-scale during the year. Valdivia the most modern and largest plant, had not fully recovered from an over $2 million fire in October 1971 and was producing at only 70 percent capacity at yearend 1972.

At $2.27 per pound, which was much higher than the Japanese price, Chile was not able to sell any iodine during 1972 in the sluggish U.S. market. It appeared also that this price was not necessarily adequate to cover cost, which had gone up sharply since the fire. Stocks were building up, and Chile's 1972 iodine sales were confined mainly to Eastern European, Western European, Latin American countries, and the Peoples Republic of China. A new price policy apparently was being considered late in the year.

Japan.—Japan strengthened its position as the world's foremost iodine producer during 1972. Its output of 8,240 short tons of crude iodine, an increase of about 11 percent over the 7,423 tons produced in 1971, was more than three times that of Chile, the only other major free world producer. Over four-fifths of the Japanese production was exported, principally to the United States, which took about 3,103 short tons in 1972. Japan's other iodine markets included Common Market countries, United Kingdom, India, the People's Republic of China, and Canada.

Japan's iodine was produced from natural gas brines by five manufacturing groups operating 18 plants. About five of the plants have been built since 1970.

As of yearend 1972, crude iodine capacity of Japan was about 650 tons per month. Ise Chemical Industries, Ltd. (Ise Chemical), was by far the leading firm, with roughly one-half of the country's capacity. It owns seven plants and produced 25 tons monthly for Teikoku Oil Co. Ltd (Teiseki) and 12 tons monthly for United Resources (Godo). Godo's two plants accounted for about one-fifth of Japan's capacity. Nippon Tennen (Nitten) with three plants and Kantoh Tennen (Kanten) with four plants each had just over one-tenth of the total capacity. The rest was owned by two sister companies—Nippon Chemical Industries and Nippon Halogen, each with one plant.

Japan's iodine producers continued to pay large dividends because of good prices. The Japan Iodine Export Corp. held down the price in the United States at $1.86 per pound despite the fact that Chilean and U.S. producers had been selling crude iodine at a much higher price during 1972. Japanese iodine prices were increased in early 1973 to a level still below its competitors. Recent price increases in Japanese iodine did not mean any benefits to the producers, however, as these were totally linked to the upward revaluation of the Yen, which remained the same in value within Japan.

The outlook for the Japanese iodine industry was not as bright as a few years ago, principally because the recent and projected price increases weaken the Japanese position and the competitive status of iodine as a commodity. The reserve picture remained essentially the same, although it would improve under conditions of high price and better technology. Japan had enough iodine in its natural gas to support recent production levels indefinitely. Output of iodine had already risen 28 percent in 1970, 14 percent in 1971, and another 11 percent in 1972. Despite subsidence and pollution difficulties in some Chiba operations, Japanese iodine production is likely to increase somewhat in the next few years, in view of the relatively low-cost resources, the steady growth in world demand, and the probability that Chilean output would not surpass historic peak levels. However, the ecological problem has become increasingly troublesome, and long-term output potential can be seriously affected. Ground control and waste disposal regulations are expected to be more strict, and reinjection of fluids into the ground is not always feasible. Only Ise Chemical has plants in new areas satisfying environmental guidelines along with the potential for substantial expansion. Ise Chemical had been investigating iodine resources in Indonesia and could eventually initiate production there under appropriate conditions.

U.S.S.R.—Soviet production of iodine has been estimated at 1.1 million pounds for 1966 and 3.3 million pounds for 1971, derived from the Neftechlinski field and the Slavyansko-Troitskoe area near the Black Sea.[4]

LITHIUM [5]

Domestic output of lithium minerals and lithium carbonate from brines increased substantially over that of 1971 and was the largest ever reported. Imports for consumption of lithium minerals were only about one-fifth the quantity imported in 1971.

Legislation and Government Programs.—The ad valorem tariff on lithium metal was 12.5% and on lithium compounds 5% during 1972; lithium minerals concentrates are imported duty free. At yearend 6,490 short tons of lithium hydroxide monohydrate were held by General Services Administration under the Federal Property Act.

Domestic Production.—Foote Mineral Co. mined and milled spodumene from pegmatites at Kings Mountain, N.C., and also recovered lithium carbonate from brines at Silver Peak, Nev. Lithium Corp. of America, a subsidiary of Gulf Resources and Chemical Corp., mined and milled spodumene near Bessemer City, N.C.; Kerr-McGee Corp. recovered lithium carbonate from brines at Trona, Calif.

Foote Mineral Co. completed expansion of its lithium carbonate production capacity at Silver Peak, Nev., during the year and construction of a commercial, low-iron spodumene facility at Kings Mountain, N.C., was completed in December.[6]

Processors of lithium raw materials to lithium primary products were Foote Mineral Co., Sunbright, Va., and Silver Peak, Nev., Kerr-McGee Corp., Trona, Calif., and Lithium Corp. of America, at Bessemer City, N.C. Production data were not available for publication.

Consumption and Uses.—Domestically produced lithium minerals were processed into numerous lithium chemicals for a wide variety of applications. Major uses were in primary aluminum production, ceramics, greases, air conditioning, alloying, welding and brazing, swimming pool sanitation, and organic synthesis.

Although consumption of most lithium compounds increased during the year, sales of lithium carbonate to the aluminum industry continued to show the most significant increase.

Humble Oil & Refining Co. announced the development of a new generation of lithium-soap greases. The new multipurpose products are said to offer extended life at high temperatures and also function well at subzero temperatures. Recommended industrial applications include oven conveyor bearings, dryer roll bearings, rotary steam joints, kiln car bearings, induced-draft fan bearings, other equipment subjected to high radiant heat, and lubricated-for-life bearings.[7]

---

[4] Page 23 of work cited in footnote 3.

[5] Prepared by Donald C. Wininger, physical scientist.

[6] Foote Mineral Co. 1972 Annual Report, p. 3.

Prices.—Domestic prices of lithium minerals are usually determined by direct negotiation between buyer and seller and are seldom published. However, the January 1972 issue of Ceramic Industry listed prices for spodumene supplied to the ceramic industry ranging from $77 to $89.50 per ton, compared with $71 to $84 quoted in 1971. The following prices[8] for lithium minerals per short ton unit Li_2O, concentrate, c.i.f. main European port were listed in the December 1972 issue of Industrial Minerals:

Amblygonite, 6–8% Li_2O (basis 8%)	$14.46–16.61
Lepidolite, 3–3.5% Li_2O (basis 3%)	$15.00–15.54
Petalite, 3.5–4.5% Li_2O (basis 3%)	$9.64–11.79
Spodumene, 4–7% Li_2O (basis 6%)	$11.04–12.86

Prices for the major lithium compounds at yearend were quoted in the Chemical Marketing Reporter as follows:

	Per pound
Lithium metal, 1,000-pound lots or more, delivered	$8.18
Lithium bromide, anhydrous, drums, ton lots, delivered	1.70
Lithium carbonate, carlots, truck loads, delivered, in drums	.525
Lithium chloride, anhydrous, carlots, truck loads, delivered, in drums	.91
Lithium fluoride, carlots, truck loads, delivered in drums	1.58–1.59
Lithium hydride, carlots, truck loads, delivered	8.05
Lithium hydroxide, monohydrate, carlots, truck loads, delivered, in drums	.63
Lithium nitrate, technical, 100-pound lots, in drums	1.25–1.55
Lithium stearate, 50-pound cartons, carlots, works, freight allowed	.58
Lithium sulfate, 100-pound lots, in drums	1.20–1.30

Foreign Trade.—Exports of lithium hydroxide increased from 478,239 pounds valued at $244,834 in 1971 to 1,097,175 pounds valued at $595,232 in 1972. Quantitative data on exports of lithium minerals and lithium metal, alloys, and other compounds were not available. Domestic imports of lithium minerals were only 19% of the 1971 level. Australia was the only source of imported ores during 1972. Imports of lithium compounds were 36,791 pounds valued at $69,291, principally from the U.S.S.R. (62%), France (36%), and small amounts from Ireland, Japan, the United Kingdom, and West Germany.

World Review.—*Canada.*—The Chemalloy Minerals subsidiary, Tantalum Mining Corp. of Canada, Ltd. obtained a loan from the Manitoba Development Corp., which will be used to construct a mill for the production of lithium concentrates. Initial plans are for the construction of a 150-ton-per-day pilot mill at the Bernic Lake mine site. If the results of this work are favorable, the plant will be expanded to between 350 and 450 tons per day.[9]

The stronger lithium carbonate and hydroxide market worldwide has prompted the Sullivan Mining Group to consider reopening its Barrute lithium mine. The mine, formerly operated under the name Quebec Lithium, has been on a care-and-maintenance basis since 1966 when it was closed due to a drop in the price of lithium carbonate and a strike for higher pay by mine employees.[10]

Italy.—Montecatini Edison S.p.A. (Montedison), which formerly manufactured lithium compounds from spodumene, has discontinued production for economic reasons.[11]

South-West Africa, Territory of [6] [e]	do	7,616	8,909	[7] 5,881
United States	not specified	W	W	W

[e] Estimate. [p] Preliminary. NA Not available. W Withheld to avoid disclosing individual company confidential data.

[1] In addition to the countries listed, others (notably the U.S.S.R.) may produce lithium minerals, but available information is inadequate to make reliable estimates of output levels.

[2] Exports.

[3] United States imports from Canada.

[4] Includes amblygonite as follows, in short tons: 1970—14; 1971—NA; 1972—NA.

[5] Output has not been reported since 1964, but presumably has continued. Figures given are simply the 1964 output level rounded to the nearest thousand tons and are presented only to indicate order of magnitude of previous production, there being no assurance that the output level has not varied (footnote 6). In 1964, total reported production was distributed as follows by mineral, in short tons: eucryptite—806; lepidolite—22,943; petalite—36,449; spodumene—6,965.

[6] Output has not been reported since 1966, but presumably has continued, inasmuch as a number of countries record imports from "South Africa," which in total considerably exceed reported output of the Republic of South Africa. Estimates given represent total reported imports from "South Africa" by the United States and the European Economic Community less the reported output of the Republic of South Africa. These quantites, however, may include significant amounts originating in Southern Rhodesia (footnote 5) rather than in the Territory of South-West Africa. In 1966, total reported production was distributed as follows, by mineral, in short tons: amblygonite—30; lepidolite—365; petalite—1,344.

[7] Imports by United States, West Germany, and Netherlands only (footnote 6).

Technology.—Interest continued to build in the development of a lithium-sulfur battery. Results of some of the various ongoing research projects relating to battery development being conducted were reported during the year.[12]

In February, Lockheed Missiles & Space Co., Palo Alto, Calif., announced the development of a battery fueled with water and a light alkali metal such as sodium or lithium. The firm claims that pound-for-pound it produces from 10 to 100 times more electricity than the commonly used lead acid battery. Lockheed says the new battery potentially is the answer for pollution-free electric autos.[13]

The use of Raman powder spectroscopy for determing solid solubility of lithium niobate and lithium tantalate was reported.[14] The results of the study are said to have important implications concerning the conditions under which crystal growth of these materials can be conducted.

Bell Laboratories has developed a clear lithium tantalate crystal, which is claimed to be the first practical alternative to quartz crystal filters in communications equipment. The crystal is being produced in Andover, Mass., at the Merrimack Valley works of the Western Electric Co.[15]

A technique to improve the reliability and durability of ceramic sonar transducers has been developed by scientists at the Naval Research Laboratory in Washington, D.C. Investigators found that small additions of lithium fluoride to barium titanate improved densification. Increases in strength of 50% and 200% were achieved when the lithium fluoride was combined with comparable additions of magnesium oxide.[16]

A report of recent studies indicates that the addition of lithium to aluminum-magnesium alloys may lower the density by as much as 10% while maintaining a high strength.[17]

The advantages of adding lithia to glass batches were reported on during the year.[18] Increased productivity without deteriorating the quality of the glass or shortening the life of the furnace was claimed. Reduced viscosity was said to be obtained at lower melting temperatures thus lowering fuel consumption and stack emissions. The savings of increased productivity and yielded longer furnace life, and improved product quality more than offset the added raw material costs.

MEERSCHAUM[19]

The quantity of meerschaum imported in 1972, primarily for domestic use in pipes and cigarette holders, declined sharply (36%) for the second straight year. United States imports for consumption totaled 11,139 pounds valued at $22,791, compared with 17,482 pounds valued at $25,825 in 1971. Sources of U.S. imports of meerschaum in 1972 were Belgium and Luxembourg, Japan, and Turkey.

QUARTZ CRYSTAL[20]

ELECTRONIC-GRADE

Total raw quartz crystal consumption increased 42% over that of 1971. The consumption of manufactured quartz continued to exceed that of natural quartz, but the consumption of both categories increased. Imports of electronic-grade material almost doubled that of 1971. Exports of both natural and manufactured material declined. The production of finished crystal units increased 22% to almost 25.6 million units.

Legislation and Government Programs.—The Government maintained a stockpile objective of 320,000 pounds of electronic-grade quartz crystal. Sales of excess material were continued by the General Services Administration. At yearend the Defense Materials Inventory declined slightly from the previous year to 4.34 million pounds of stockpile-grade material and 352,960 pounds of nonstockpile-grade material.

Domestic Production.—No production of natural electronic-grade quartz crystal was reported during 1972. At yearend, six companies reported production of manufactured quartz for use by the quartz crystal cutting industry. These companies were P.R. Hoffman Co., Carlisle, Pa.; Motorola, Inc., Chicago, Ill.; Quality Crystals, Inc., Cortland, Ohio; Sawyer Research Products, Inc., Eastlake, Ohio; Thermodynamics Corp., Shawnee Mission, Kans.; and Western Electric Co., Inc., North Andover, Mass. The firms producing manufactured quartz remained unchanged from the previous year. Manufactured quartz production increased 45% from the quantity reported in 1971 to 159,825 pounds.

Consumption and Uses.—Total raw crystal consumption increased significantly from 132,739 pounds in 1971 to 189,078 pounds in 1972. Consumption of natural quartz increased 41% from 61,784 pounds in 1971 to 87,157 pounds in 1972. Manufactured quartz consumption increased 44% from 70,955 pounds in 1971 to 101,921 pounds in 1972. The consumption of manufactured quartz exceeded that of natural quartz for the second consecutive year. The number of finished crystal units fabricated from the raw quartz consumed during the year reached almost 25.6 million units. The 1972 consumption data reported in table 5 are based on reports received from 28 crystal cutters in 12 States. Finished piezoelectric units were produced by 24 of the cutters; the remainder produced only semifinished blanks. Of these cutters 2 consumed natural quartz only, 14 cut manufactured quartz only, and 12 cut both natural and manufactured quartz.

Table 5.—Salient electronic- and optical-grade quartz crystal statistics

(Thousand pounds and thousand dollars)

	1970	1971	1972
Production of manufactured quartz	131	110	160
Imports of electronic- and optical-grade quartz crystal			
Quantity	94	35	65
Value	100	76	78
Exports of electronic- and optical-grade quartz crystal			
Quantity	286	174	149
Value	1,123	1,626	1,228
Natural:			
Quantity	231	113	90
Value	396	833	587
Manufactured:			
Quantity	55	61	59
Value	727	793	641
Consumption of raw electronic-grade quartz crystal	165	133	189
Natural	98	62	87
Manufactured	67	71	102
Production, piezoelectric units, number	18,971	20,924	25,555

Thirteen consumers in four States accounted for almost 90% of the raw quartz crystal consumption. Pennsylvania was the leading quartz-consuming State with 46% of the total, followed by Illinois, Kansas, and Missouri. Piezoelectric units were manufactured by 34 producers in 15 States. Eleven of these producers worked from partially processed quartz crystal blanks and did not consume raw material. Twelve plants in four States, Kansas, Illinois, Pennsylvania, and Missouri, supplied 77% of the total output of finished crystal units. Oscillator plates comprised 81% of production. The remainder included filter plates, telephone resonator plates, and other micellaneous items.

Stocks.—At yearend, stocks of raw quartz crystals held by consumers totaled 96,133 pounds. Of this total 73,832 pounds was natural material, and the remainder was manufactured quartz.

Foreign Trade.—The imports of electronic- and optical-grade quartz crystal, valued at more than $0.50 per pound, increased in both quantity and value in 1972 to 65,135 pounds and $78,462, respectively. This was an 86% increase in quantity but only 3% in value from the previous year's totals. The average value of imports was $1.20 per pound, a sharp decline from the previous year's average value of $2.17 per pound. Brazil supplied 91% of the total imports of electronic-grade material. The remainder was supplied by the United Kingdom and West Germany. The quartz crystal imported from these countries probably originated in Brazil.

A total of 684,617 pounds of lasca valued at $252,531 was inported in 1971, a decline of 5% in quantity and 13% in value from 1971 figures. Lasca was used to produce fused quartz and as a nutrient material for the manufacture of quartz crystal. Brazil provided 98% of total imports, and the remainder was shipped from West Germany and Japan.

U.S. exports of natural quartz crystal declined 20% from 112,560 pounds in 1971 to 90,246 pounds in 1972. Exports of manufactured quartz declined slightly from 60,750 pounds in 1971 to 58,914 pounds in 1972. The average price of natural quartz exported was $6.51 per pound; that of manufactured quartz was $10.89 per pound.

World Review.—*Brazil.*—The Nation maintained its position as the dominant world producer of electronic-grade quartz crystal and lasca. Exports of quartz crystal suitable for electronic use totaled 152,000 pounds valued at $279,000 in 1971. In addition, almost 10 million pounds of lasca valued at $2.33 million was exported.

Technology.—Two reports of experimental work have been published relating the quality of quartz crystal to infrared absorption.[21] A new method was described using a strain gauge to measure the mechanical strain in quartz crystals under the influence of an applied d.c. field. The piezoelectric constants increased with the applied voltage. These measurements were used to determine the quality of raw uncut quartz crystals.[22]

STAUROLITE [23]

Staurolite is a complex iron-aluminum silicate of uncertain and most likely variable composition. The mineral occurs as reddish-brown to black crystals with a specific gravity ranging from 3.65 to 3.77 and between quartz and topaz in hardness (7 to 8 on Moh's scale). Aside from a small rock-shop trade in cruciform-twinned crystals from some deposits ("fairy crosses") that are sold as curiosities or amulets, staurolite is produced commercially in the United States only in the form of a magnetic fraction of the heavy-mineral concentrate recovered by E. I du Pont de Nemours & Co. from a beach sand deposit in Clay County, Fla. Formerly the staurolite fraction was used only in some portland cement mixtures, but more recently this product (with minor admixtures of kyanite, quartz, rutile, spinel, tourmaline, and zircon, and averaging 45% Al_2O_3 and 15% Fe_2O_3) is being marketed under two trade names either for use as a sandblast abrasive or to be mixed with bentonite and other substances to serve as a foundry sand in some specialized molding applications. Increasing industrial demand for these products can be inferred from the observation that the ratio of staurolite shipments to staurolite production (which averaged around 50% in the 1965 to 1969 period) has been substantially in excess of 100% in each of the last 3 years. Quantitative production and shipment data are not released for publication, but the 1972 staurolite output was 4% below that of 1971, while shipments increased fractionally in tonnage and 11% in total value.

STRONTIUM [24]

Legislation and Government Programs.—Government stockpiles contained 12,062 tons of stockpile-grade and 13,787 tons of nonstockpile-grade celestite at yearend. The General Services Administration again offered the celestite for sale, however, no acceptable bids were received during the year.

Domestic Production.—Strontium minerals have not been produced commercially in the United States since 1959. However, a number of firms produced various strontium compounds from imported celestite. Sherwin-Williams Co., Ashtabula, Ohio, discontinued production of strontium carbonate at the end of August.

Consumption and Uses.—Domestic consumption of celestite in the manufacture of various strontium chemicals declined from the 1971 high. Quantitative information concerning consumption is incomplete, however, production of strontium carbonate was 15,476 short tons, compared with 19,350 tons produced in 1971. Sales of domestically produced strontium carbonate to manufacturers of glass for color television picture tubes totaled 15,030 short tons, a 3% decrease from those of 1971. Consumption of celestite in the manufacture of chemicals for pyrotechnics was not available.

Miscellaneous chemical applications for strontium compounds included ferrites, greases, ceramics, plastics, toothpaste, pharmaceuticals, paint, and electronic components. Small quantities of strontium metal were produced for use primarily by research companies. King Laboratories, Inc., Syracuse, N.Y., consumed a small quantity of metal to produce getter alloys used in the manufacture of vacuum tubes.

Prices.—At yearend, prices quoted in the Chemical Marketing Reporter were as follows: strontium carbonate:—technical, bags, carlots, works, at 13 to 21 cents per pound; and strontium nitrate:—bags, carlots, works, at $15 per 100 pounds, unchanged from the previous year. Prices for strontium minerals are usually determined by direct negotiation between buyer and seller and are seldom published. However,

Grand total	215,823	48,437	1,283,972	217,351

the December 1972 issue of Industrial Minerals listed the following price for British celestite: ground, washed and graded, 95% $SrSO_4$, bulk, exworks, 240-mesh $47.90 per short ton[25] the average value of imported strontium minerals at foreign ports was about $27 per short ton.

Foreign Trade.—Imports of strontium minerals totaled 30,677 tons, a 33% decline from the 1971 high. The material was imported from Mexico and the United Kingdom. Imports of strontium compounds increased six times over those of 1971 with most of the material coming from Canada (84%). Quantitative data on U.S. exports of strontium compounds were not available.

[e] Estimate. [p] Preliminary. [r] Revised

[1] In addition to the countries listed, West Germany, Poland, and the U.S.S.R. produce strontium minerals, but available information is inadequate to make reliable estimates of output levels.

[2] Year beginning March 21 of that stated.

[3] U.S. imports from Mexico.

World Review.—*Canada.*—Kaiser Strontium Products Ltd. began full scale worldwide marketing of strontium chemicals from its new plant at Point Edward, Cape Breton Island, Nova Scotia. Startup problems, however, delayed commercial-scale production of glass-grade strontium until the later part of the year.

Turkey.—A large deposit of high-grade, good-quality celestite has been discovered about 15 miles south of Siuas. Shipments to Europe and elsewhere are anticipated to commence in the near future.[26]

Technology.—A number of papers were presented at the annual meeting of the American Ceramic Society, concerning research on various strontium compounds, which may have electrical or electronic applications.[27]

The results of experiments on the formation of thin layers of mixed titanates including strontium by solid-solid reactions were reported. Possible application in devices such as delay lines, slow wave structures, and optical modulators was suggested.[28]

WOLLASTONITE [29]

Wollastonite, occurring naturally in certain deposits with a purity exceeding that of most other industrial minerals, is a crystalline calcium metasilicate that is finding increasing acceptance by industry as an ingredient with many advantages in ceramic body mixes, glazes, and enamel frits; as a filler for plastics, rubber, and asphalt products; as a pigment and extender for paints; in welding as a flux and rod coating; and presumably in a number of other applications still too new to have become generally known.[30]

Wollastonite was produced in the United States in 1972 from one open-pit mine operated by Interpace Corp. at Willsboro, Essex County, N.Y. Output from that mine was 35% greater in tonnage than in 1971, and the corresponding total value was 57% higher. Both figures represented new alltime highs for the New York mine, and it is notable that the tonnage was only 10% below the record national total of 1966 (when California also made a substantial contribution), and that the 1972 total value was also an alltime national high, 22% above that of 1966.

Wollastonite prices per short ton, works, were quoted in the Chemical Marketing Reporter on December 25, 1972, as follows: fine, paint-grade, bags, carlots, $43.80; and medium, paint-grade, bags, carlots, $33.00. These quotations were unchanged from those of the previous year. For the most part, actual sales were arranged as usual at negotiated prices not on public record.

A number of raw materials (including wollastonite, pyrophyllite, and clays), as well as the technologically advanced methods and equipment recommended for efficiently fabricating them into ceramic tile, were discussed in a journal article.[31] Another article mentioned the advantages of using wollastonite in glazes for tile to prevent excessive bubble formation and still assure maturing of the ware within an accelerated firing cycle.[32] Experiments were carried out to study the preparation of materials with hydraulic setting properties by the calcination of calcium carbonate-silica mixtures produced either by carbonation of wollastonite and pseudowollastonite (a dimorphous form, also called betawollastonite), or alternatively by intergrinding precipitated $CaCO_3$ with SiO_2 flour.[33]
